Castle Key Indemnity Company
Condominium
Company Filing Number: R55174
Rate Change

With this filing, Castle Key is proposing an overall 53.5% rate level change to the Castle Key Indemnity Company (CKI) Homeowners - Condominium (CON) program in the state of Florida.

Castle Key is also proposing revisions to the following rating plans: Hurricane and Non-Hurricane Territorial Relativities. The overall rate level change has been achieved through revision of the Hurricane and Non-Hurricane Base Rates and Hurricane and Non-Hurricane Coverage A Factors. Further information regarding these changes can be found in the enclosed attachments.

This change will apply to all business effective on or after May 14, 2023.

This filing company is closed to new business. Castle Key has, however, supplied a new business effective date for special business cases. For example, to accommodate a new business policy in the same company to a policyholder that has been reinstated, or if a cancel/re-write is necessary.

If you have any questions or concerns, please feel free to contact me at jolst@allstate.com or at (847) 402-5617.

Sincerely,

Jennifer Olson
State Filings Consultant

CASTLE KEY INDEMNITY COMPANY

EXPLANATORY MEMORANDUM

With this filing, Castle Key Indemnity Company is proposing an overall increase of 53.5% to its Condominium insurance program. This change will be accomplished by revising the Non-Hurricane and Hurricane Base Rates, as well as the Non-Hurricane and Hurricane Coverage A Rates. For the Base Premium and Coverage A Premium calculation, Castle Key is proposing changes to the Non-Hurricane and Hurricane Territorial Relativities rating plans.

Castle Key's product team has informed the OIR of our intention to non-renew some CKI Condo policies. A final decision on which policies to non-renew has been made and communicated with the OIR. Adjustments have been made to the data in the indication and measurement to reflect the non-renewals.

The filing components that will aid the review of the Rate Level Indication and proposed changes are summarized below. Castle Key recommends using Attachment A – Indication Filing Memo as the primary guide for reviewing the Rate Level Indication.

Indication Filing Memo

- **Attachment A – Indication Filing Memo** provides explanatory support for all components of the indication.
- **Attachment B – Supporting Exhibits** provides numerical support for all components of the indication.
- **Attachment C – Trends** provides regressions for loss, premium, and exposure trends.
- **Attachment D – Expenses** provides support for underwriting expenses, unallocated loss adjustment expense, and reinsurance expense.
- **Attachment E – FL Profit Provision** provides the underwriting profit under FAC 69O-170.
- **Attachment F – DUPP Exhibits** provides the development of Castle Key's internal underwriting profit provision.
- **Attachment G – Non-Modeled Catastrophes –** provides the development of the non-modeled catastrophe provision.

Rate Support by Territory

- The **Territory Support Memo** provides information regarding the Territorial Definitions and Relativities.

Other Rating Factor Changes

- The **Other Rating Factor Changes Memo** provides information regarding the other changes to the rating plans.

Manual Pages, Catastrophe Model Support, Reinsurance Expense Support, and the required OIR filing forms, rating examples, and exhibits are provided in the respectively titled folders.

Annual Rate Certification

Pursuant to Section 627.0645, this filing has been made to comply with the annual rate filing requirements. The name and title of the Certifying Actuary or Experienced Company Ratemaker who reviewed the rate filing are as follows:

Samantha Steiner, FCAS, MAAA
Senior Actuary

Pursuant to section 627.062, Florida Statutes, we are ready to provide additional or supplementary information pursuant to a formal or informal request from the Office.

Date:	03/20/2023
Filing Id:	1220887

Interrogatory Component Name:	Interrogatories
Interrogatory:	Homeowners Rates

Question #	Question	Answer
1	Are you someone other than an employee of the company who is making this filing on behalf of the company?	No
2	Is this filing being made to comply with a change in Florida law?	No
3	Does this filing propose changes in the level of coverage you are providing to your insureds?	No
4	Is this filing being made to adjust rates for an existing program with business?	Yes
5	Does this filing include the use of a Catastrophe Model in the determination of any rate level indication?	Yes
6	Does this filing include rates or rating factors that result in a rate change to the Office's RCS rating examples OR is there an overall rate change associated with this filing OR does this filing include the introduction of a new program?	Yes
7	Does this filing propose changes in any rating factor other than base rates (or relativities) by territory?	Yes
8	Do you offer policies excluding wind coverage?	Yes
9	Does your company use credit information, credit reports or credit/insurance scores in underwriting or rating (including any categorization that would affect the premium charged to the insured)?	Yes

DEVELOPMENT OF NON-HURRICANE ZONE RELATIVITIES
EXPLANATORY MEMORANDUM

With this filing, Castle Key Indemnity Company (CKI) is updating factors for the Non-Hurricane Zone Relativities applicable to base premium. The numerical references in this memorandum correspond to the numbering sequence on the respective exhibits.

Please note that data from policies that will be non-renewed has been removed from all calculations.

Territory Support Exhibit 1.1 – Non-Hurricane Zone Current Relativities

(1a) Zip Code

(1b) Zip Code Group
Castle Key's base territorial factors are nearly at the zip code level. However, due to systems constraints, some zip codes are grouped into zip code groups for the purpose of rating.

(1c) Water Peril Zone
Zip codes were grouped into 9 zones for the water peril. Castle Key is utilizing the Water Peril Zones in the complement of credibility calculation in this territorial analysis due to water being the leading peril in CKI Condo loss experience thus far.

(2) Earned Premium
This shows CKI Earned Premium not at Current Rate Level by zip from fiscal accident years ending June 30, 2020 to 2022. The statewide total reconciles to the total Earned Premium in column (5) of the RIF. Please note that these Earned Premiums are provided per the Territorial Instructions. However, they are not used in the calculations. Instead, Castle Key uses the current average non-hurricane variable premiums in column (3). Given the frequency with which Castle Key revises territorial relativities, it is more accurate and efficient to utilize the in-force premiums at current rate level than to current rate level historical earned premiums by territory.

(3) Current On-Level Average Non-Hurricane Variable Premium:
These are the current average non-hurricane variable premiums. In parts (3a)-(3c), it is aggregated at a zip, zip group, and peril zone level. Part (3d) selects which current average premium to use for each zip. Zip group-level average non-hurricane premium is

used if a zip group has enough exposures. In cases where there are low exposures in a zip group, the average non-hurricane premium for the corresponding peril zone is substituted. The criteria used to determine low exposure is less than 15 exposures.

The purpose of this information is to capture each zip code group's premium differences based on the current non-hurricane rates. The data is in-force as of October 27, 2022.

(4a) Current Exposure Count (Zip)
The data is in-force as of October 27, 2022.

(4b) Current Exposure Distribution: (4a) / (4a) Statewide

(4c) Current Exposure Count (Zip Group)

(5) Average Non-Hurricane Variable Premium Relativities: (3d) / (3d) Statewide
An average non-hurricane variable premium relativity for each zip code is derived by dividing the selected on-level average non-hurricane variable premium for each zip code by the statewide average non-hurricane variable premium.

Territory Support Exhibit 1.2 – Non-Hurricane Zone Indicated Premium Relativities

(1a) Zip Code: Same as Exhibit 1.1

(1b) Zip Code Group: Same as Exhibit 1.1
Castle Key's base territorial factors are nearly at the zip code level. However, due to systems constraints, some zip codes are grouped into zip code groups for the purpose of rating.

(1c) Water Peril Zone: Same as Exhibit 1.1

(2) Current Exposure Distribution: Same as Exhibit 1.1, Column (4b)

(3) Average Non-Hurricane Variable Premium Relativities: Same as Exhibit 1.1, Column (5)

(4) Paid Claims (Zip Code Group):
This includes CKI non-catastrophic paid claims by zip code group from fiscal accident years ending June 30, 2020 to 2022.

(5) Earned Exposures (Zip Code Group):
This includes CKI earned exposures by zip code group from fiscal accident years ending June 30, 2020 to 2022. The statewide total reconciles to the total Earned House Years in column (3) of the RIF.

(6) Non-Catastrophe Incurred Losses (Zip Code Group):
This includes CKI non-catastrophic incurred loss and allocated loss adjustment expense by zone from fiscal accident years ending June 30, 2020 to 2022. To isolate the territorial signal applicable to base premium, Coverage A losses were capped at 30% of the Coverage C limit for the base territorial analysis.

The sum of the statewide total of Exhibit 1.2, Column (6) and Exhibit 3.1, Column (7) reconciles to the sum of the total non-catastrophe incurred loss and allocated loss adjustment expense found in columns (12) and (16) of the RIF.

(7) Non-Catastrophe Pure Premium (Zip Code Group): (6) / (5)
This shows the average non-catastrophic incurred losses and allocated loss adjustment expense per earned exposure by zip code group.

(8) Non-Catastrophe Pure Premium Relativities: (7) / (7) Statewide
A non-catastrophe pure premium relativity for each zone is derived by dividing the non-catastrophe pure premium for each zone by the statewide non-catastrophe pure premium.

(9) Balanced Non-Catastrophe Pure Premium Relativities: (8) / (8) Statewide
The statewide non-catastrophe pure premium relativity in column (8) is derived by weighting the zone-specific non-catastrophe pure premium relativities with the corresponding current exposures distribution in column (2). The zip code group-specific relativities are re-balanced so that the statewide relativity is 1.000.

(10) Credibility:
The calculated credibility is based upon a credibility procedure from the paper "On the Credibility of the Pure Premium" (Proceedings of the Casualty Actuarial Society, Vol. LV, 1968), by Mayerson, Jones and Bowers, and the appendix of the paper "Classical Partial Credibility with Application to Trend" (Proceedings of the Casualty Actuarial Society, Vol. LXXIII, 1986), by Venter. The analysis made the commonly accepted assumption that frequency follows a Poisson distribution. The analysis was completed using a P value of 90.0% and a k value of 0.10; these parameters reflect the desire that the observed pure premium should be within 100k% of the expected pure premium with probability P.

If a zip code group has less than 15 exposures, credibility is overridden to 0.0%. This is the same threshold that was used to select the current relativity for each zip code group in Exhibit 1.1. Since zip groups with few exposures are using Water Peril Zones for their current premium relativities instead of zip code group data, it is appropriate that only Water Peril Zone loss relativities are used. To achieve this, the zip code group's credibility is set to 0.0%.

(11) Paid Claims (Water Peril Zone):

The paid claims by zone group is developed the same way as column (4) but aggregated to the peril zone level.

(12) Non-Catastrophe Pure Premium (Water Peril Zone):
The non-catastrophe pure premium relativities by zone group are developed the same way as column (7) but aggregated to the peril zone level.

(13) Non-Catastrophe Pure Premium Relativities (Water Peril Zone):
The non-catastrophe pure premium relativities by zone group are developed the same way as column (8) but aggregated to the zone group level.

(14) Balanced Non-Catastrophe Pure Premium Relativities (Water Peril Zone): (13) / (13) SW
The statewide non-catastrophe pure premium relativity in column (13) is derived by weighting the zone-specific non-catastrophe pure premium relativities with the corresponding current exposure distribution in column (2). The peril zone-specific relativities are re-balanced so that the statewide relativity is 1.000.

(15) Credibility (Water Peril Zone):
The credibility by peril zone is developed the same way as column (10) but calculated using the peril zone level paid claims. This credibility is not overridden to 0.0% for low exposure groups.

(16) Complement of Credibility: [(14) x (15)] + [(3) x (1 – (15))]
Using credibility calculated in (15), non-catastrophe pure premium relativity by zone group is weighted against the implied non-catastrophe pure premium relativity by zone to determine the complement of credibility by zone.

(17) Balanced Complement of Credibility: (16) / (16) Statewide
The statewide complement of credibility relativity in column (16) is derived by weighting the zone-specific complement of credibility relativities with the corresponding current exposures distribution in column (2). The zip code group-specific relativities are re-balanced so that the statewide relativity is 1.000.

(18) Credibility Weighted Non-Catastrophe Pure Premium Relativities: [(9) x (10)] + [(17) x (1 – (10))]
Using credibility calculated in (10), non-catastrophe pure premium by zone is weighted against the balanced complement of credibility by zone to determine the credibility weighted non-catastrophe pure premium by zip code group.

(19) Balanced Credibility Weighted Non-Catastrophe Pure Premium Relativities: (18) / (18) Statewide
The statewide credibility weighted non-catastrophe pure premium relativity in column (18) is derived by weighting the zip code group-specific credibility weighted non-catastrophe pure premium relativities with the corresponding current exposures in column (2). The zone-specific relativities are re-balanced so that the statewide relativity is 1.000.

Territory Support Exhibit 1.3 – Non-Hurricane Zone Relativity Changes

(1) Zip Code: Same as Exhibit 1.1, Column (1a)

(2) Average Non-Hurricane Variable Premium Relativities: Same as Exhibit 1.1, Column (5)

(3) Balanced Credibility Weighted Non-Catastrophe Pure Premium Relativities:
Same as Exhibit 1.2, Column (19)

(4) Indicated Zone Relativity Change: (3) / (2) – 1
The indicated relative rate changes by zone are derived by comparing the balanced credibility weighted non-hurricane pure premium relativities with average non-hurricane variable premium relativities.

(5) Proposed Non-Hurricane Zone Relativity Change:
The proposed non-hurricane zone relativity changes were targeted to move 50% towards indicated values with a threshold indication of +/- 5% and a capped proposed change of +/- 20%. The relative changes were selected to reflect emerging loss experience while attempting to mitigate policyholder impacts.

(6) Current Non-Hurricane Zone Relativities

(7) Indicated Non-Hurricane Zone Relativities: (6) * (1 + (4))
The new relativities after the proposed relativity changes are applied to current relativities.

(8) Proposed Non-Hurricane Zone Relativities: (6) * (1 + (5))
The new relativities after the proposed relativity changes are applied to current relativities.

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM
FLORIDA

DEVELOPMENT OF HURRICANE ZONE RELATIVITIES
EXPLANATORY MEMORANDUM

With this filing, Castle Key Indemnity Company (CKI) is updating factors for the Hurricane Zone Relativities applicable to base premium. The numerical references in this memorandum correspond to the numbering sequence on the respective exhibits.

The modeled hurricane Average Annual Loss by zone in this analysis are developed based on AIR US Hurricane Model v1.0.0 (Florida Regulatory) in Touchstone 2022 with exposures in-force as of June 30, 2022 consistent with the statewide rate level indication. The model was run two separate times to produce output for two scenarios.

- Scenario 1: Coverage C and Coverage A levels left at actual coverage amount purchased by the policyholder.
- Scenario 2: Coverage A Limits set to the Base Limit (30% of Coverage C)

To isolate the territorial signal applicable to base premium, Scenario 2 was used for the base territorial analysis.

Please note that data from policies that will be non-renewed has been removed from all calculations.

Territory Support Exhibit 2.1 – Hurricane Zone Current Premium Relativities

(1a) Zip Code

(1b) Zip Code Group
Castle Key's base territorial factors are nearly at the zip code level. However, due to systems constraints, some zip codes are grouped into zip code groups for the purpose of rating.

(1c) Wind Peril Zone
Zip codes were grouped into 11 zones for the wind peril. Castle Key is utilizing the Wind Peril Zones as an alternative grouping in this territorial analysis for low exposure zip code groups.

(2) Current On-Level Average Hurricane Variable Premium:

These are the current average hurricane variable premiums. In parts (2a)-(2c), it is aggregated at a zip, zip group, and peril zone level. Part (2d) selects which current average premium to use for each zip. Zip group-level average hurricane premium is used if a zip group has enough exposures. In cases where there are low exposures in a zip group, the average hurricane premium for the corresponding peril zone is substituted. The criteria used to determine low exposure is less than 15 exposures.

The purpose of this information is to capture each zip code group's premium differences based on the current hurricane rates. The data is in-force as of October 27, 2022.

(3) Current Exposure Distribution

(4) Average Hurricane Variable Premium Relativities: (2d) / (2d) Statewide
An average hurricane variable premium relativity for each zip code is derived by dividing the selected on-level average hurricane variable premium for each zone by the statewide average hurricane variable premium.

Territory Support Exhibit 2.2 – Hurricane Zone Indicated Premium Relativities

(1a) Zip Code: Same as Exhibit 2.1

(1b) Zip Code Group: Same as Exhibit 2.1
Castle Key's base territorial factors are nearly at the zip code level. However, due to systems constraints, some zip codes are grouped into zip code groups for the purpose of rating.

(1c) Wind Peril Zone: Same as Exhibit 2.1

(2) Current Exposure Distribution: Same as Exhibit 2.1, Column (3)

(3) Standard Model Average Annual Loss (AAL) & LAE (Zip Code):
The Average Annual Loss is the result of the AIR US Hurricane Model v1.0.0 (Florida Regulatory) in Touchstone 2022 with exposures in-force as of June 30, 2022. The AAL comes from Scenario 2 of the model run which sets Coverage A limits to the base limit. The AAL is grossed up by a 20% LAE load as supported in the Indication Filing Memo. The sum of the statewide total of Exhibit 2.2, Column (3) and Exhibit 4.1, Column (8) reconciles to the Projected Hurricane Loss and LAE in column (33) of the RIF.

(4) Policies in Force (Policies that Incl Wind) (Zip Code):
Policies in-force as of June 30, 2022 which underly the AIR Modeled results.

(5) Expected Hurricane Catastrophe Loss (Zip Code): (3) / (4)

The expected hurricane catastrophe loss per exposure by zone is developed by dividing the modeled hurricane AAL and LAE by the policies in force for each zip code.

(6) Standard Model Average Annual Loss (AAL) & LAE (Zip Code Group):
Results from column (3) aggregated at the zip code group level.

(7) Policies in Force (Policies that Incl Wind) (Zip Code Group):
Results from column (4) aggregated at the zip code group level.

(8) Expected Hurricane Catastrophe Loss (Zip Code Group): (6) / (7)
The expected hurricane catastrophe loss per exposure by zone is developed by dividing the modeled hurricane AAL and LAE by the policies in force for each zip code group

(9) Standard Model Average Annual Loss (AAL) & LAE (Wind Peril Zone):
Results from column (3) aggregated at the peril zone level.

(10) Policies in Force (Policies that Incl Wind) (Wind Peril Zone):
Results from column (4) aggregated at the peril zone level.

(11) Expected Hurricane Catastrophe Loss (Wind Peril Zone): (9) / (10)
The expected hurricane catastrophe loss per exposure by peril zone is developed by dividing the modeled hurricane AAL and LAE by the policies in force for each peril zone.

(12) Selected Expected Hurricane Catastrophe Loss:
If a zip code group's number of in-force exposures is greater than or equal to 15, the expected hurricane catastrophe loss for the zip code group is selected. However, if a zip code group's number of in-force exposures is less than 15, then the expected hurricane catastrophe loss of the corresponding peril zone is selected to mitigate distortions in expected hurricane catastrophe losses for zip code groups with low exposures. Given that zip codes within each peril zone should have similar hurricane risk, the expected hurricane catastrophe losses for these zip codes should be similar to their corresponding peril zones as well.

(13) Balanced Hurricane Catastrophe Loss Relativities: (12) / (12) Statewide
A hurricane catastrophe loss relativity for each zone is derived by dividing the hurricane catastrophe losses for each zip code by the statewide hurricane catastrophe losses. The statewide hurricane catastrophe loss in column (12) is derived by weighting the selected zip code hurricane catastrophe losses with the corresponding current exposures in column (2). Because of this, the zip code relativities are already balanced so that the statewide relativity is 1.000.

Territory Support Exhibit 2.3 – Hurricane Zone Relativity Changes

(1) Zip Code: Same as Exhibit 2.1, Column (1a)

(2) Average Hurricane Variable Premium Relativities: Same as Exhibit 2.1, Column (4)

(3) Balanced Hurricane Catastrophe Relativities: Same as Exhibit 2.2, Column (13)

(4) Indicated Zone Relativity Change: (3) / (2) – 1
The indicated relative rate changes by zone are derived by comparing the balanced hurricane pure premium relativities with average hurricane variable premium relativities.

(5) Proposed Hurricane Zone Relativity Change:
The proposed hurricane zone relativity changes were targeted to move 50% towards indicated values with a threshold indication of +/- 5% and a capped proposed change of +/- 20%. The relative changes were selected to reflect emerging loss experience while attempting to mitigate policyholder impacts.

(6) Current Hurricane Zone Relativities

(7) Indicated Hurricane Zone Relativities: (6) * (1 + (4))
The indicated relativities after the indicated relativity changes are applied to current relativities.

(8) Proposed Hurricane Zone Relativities: (6) * (1 + (5))
The new relativities after the proposed relativity changes are applied to current relativities.

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM
FLORIDA

DEVELOPMENT OF NON-HURRICANE COVERAGE A RELATIVITIES
EXPLANATORY MEMORANDUM

With this filing, Castle Key Indemnity Company (CKI) is updating factors for the Non-Hurricane Coverage A Relativities. The numerical references in this memorandum correspond to the numbering sequence on the respective exhibits.

Please note that data from policies that will be non-renewed has been removed from all calculations.

Territory Support Exhibit 3.1 – Non-Hurricane Coverage A Relativities

(1) Territory
Non-Hurricane relativities are assigned at the zip level, but zip codes are grouped into territories for the analysis. The territories used in the filing that introduced Non-Hurricane Coverage A Relativities (filing #20-031100) were utilized in this analysis.

(2) Current On-Level Non-Hurricane Additional Coverage A Premium
These are the aggregate current non-hurricane Coverage A premiums by territory. The data is in-force as of October 27, 2022.

(3) Current Additional Coverage A Purchased ($000s)
These are the aggregate current Coverage A amounts purchased by territory. The data is in-force as of October 27, 2022.

(4) Current On-Level Average Non-Hurricane Variable Coverage A Premium per $000 of Additional Coverage A: (2) / (3)
These are the current average non-hurricane Coverage A premiums by territory. The purpose of this information is to capture each territory's premium differences based on the current non-hurricane rates. The data is in-force as of October 27, 2022.

(5) Average Non-Hurricane Coverage A Premium Relativities: (4) / (4) Statewide
An average non-hurricane Coverage A variable premium relativity for each territory is derived by dividing the selected on-level average non-hurricane variable premium for each territory by the statewide average non-hurricane variable premium.

(6) Historical Additional Coverage A Paid Claims

This includes CKI non-catastrophic paid claims that have Coverage A losses which exceed the base Coverage A limit (30% of Coverage C limit) from fiscal accident years ending June 30, 2020 to 2022.

(7) Historical Additional Coverage A Loss
This includes CKI non-catastrophic Coverage A incurred loss that exceeds the base Coverage A limit (30% of Coverage C limit) from fiscal accident years ending June 30, 2020 to 2022.

The sum of the statewide total of Exhibit 1.2, Column (6) and Exhibit 3.1, Column (7) reconciles to the sum of the total non-catastrophe incurred loss and allocated loss adjustment expense found in columns (12) and (16) of the RIF.

(8) Historical Additional Coverage A Purchased ($000s)
These are the aggregate Coverage A amounts purchased by territory from fiscal accident years ending June 30, 2020 to 2022.

(9) Raw Coverage A Rate per $1,000: (7) / (8)
A raw Coverage A rate per $1,000 of additional Coverage A is derived by dividing the historical additional Coverage A losses by the historical additional Coverage A purchased ($000s). The raw rate does not include any loadings for expenses but can be used to determine the territorial relativities.

(10) Coverage A Rate Relativity: (9) / (9) Statewide
A non-catastrophe additional Coverage A rate relativity for each territory is derived by dividing the raw Coverage A rate per $1,000 for each territory by the statewide raw Coverage A rate.

The statewide raw Coverage A rate in column (9) is derived by weighting the territory-specific raw Coverage A rates with the corresponding current additional Coverage A purchased in column (3). Therefore, the territory-specific relativities are balanced so that the statewide relativity is 1.000.

(11) Credibility
The calculated credibility is based upon a credibility procedure from the paper "On the Credibility of the Pure Premium" (Proceedings of the Casualty Actuarial Society, Vol. LV, 1968), by Mayerson, Jones and Bowers, and the appendix of the paper "Classical Partial Credibility with Application to Trend" (Proceedings of the Casualty Actuarial Society, Vol. LXXIII, 1986), by Venter. The analysis made the commonly accepted assumption that frequency follows a Poisson distribution. The analysis was completed using a P value of 90.0% and a k value of 0.10; these parameters reflect the desire that the observed pure premium should be within 100k% of the expected pure premium with probability P.

(12) Complement of Credibility
The average non-hurricane Coverage A premium relativities are used as the complement of credibility by territory.

(13) Credibility Weighted Coverage A Rate Relativity: (10) * (11) + (12) * (1 – (11))
Using credibility calculated in (11), non-catastrophe additional Coverage A rate relativity by territory is weighted against the complement of credibility to determine the credibility weighted Coverage A rate relativity by territory.

(14) Balanced Credibility-Weighted Coverage A Rate Relativity: (13) / (13) Statewide
The statewide credibility weighted Coverage A rate relativity in column (13) is derived by weighting the territory-specific credibility weighted Coverage A rate relativities with the corresponding current additional Coverage A purchased in column (3). The territory-specific relativities are re-balanced so that the statewide relativity is 1.000.

(15) Indicated Relativity Change excluding the Offset Factor: (14) / (5) - 1

(16) Proposed Relativity Change excluding the Offset Factor
The proposed non-hurricane Coverage A relativity changes (excluding any offset) were derived by targeting the full territory indication.

(17) Proposed Relativity Change including Offset Factor: (1 + (16)) * Offset - 1
The Coverage A relativities account for both the territorial segmentation and the overall rate level. The proposed relativity changes are uniformly adjusted by an offset factor to achieve the targeted rate change to the Non-Hurricane Coverage A Premium.

(18) Current Non-Hurricane Coverage A Rate Per $1,000

(19) Proposed Non-Hurricane Coverage A Rate Per $1,000: (18) * (1 + (17))
The new rates after the proposed relativity changes are applied to current rates.

Territory Support Exhibit 3.2 – Non-Hurricane Coverage A Relativity Changes

(1) Zip Code

(2) Territory
Zip codes are mapped to the territories used in Exhibit 3.1.

(3) Indicated Relativity Change excluding the Offset Factor: Same as Exhibit 3.1 Column (15)

(4) Proposed Relativity Change excluding the Offset Factor: Same as Exhibit 3.1 Column (16)

(5) Proposed Relativity Change including Offset Factor: Same as Exhibit 3.1 Column (17)

(6) Current Non-Hurricane Coverage A Rate Per $1,000: Same as Exhibit 3.1 Column (18)

(7) Proposed Non-Hurricane Coverage A Rate Per $1,000: Same as Exhibit 3.1 Column (19)

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM
FLORIDA

DEVELOPMENT OF HURRICANE COVERAGE A RELATIVITIES
EXPLANATORY MEMORANDUM

With this filing, Castle Key Indemnity Company (CKI) is updating factors for the Hurricane Coverage A Relativities applicable to base premium. The numerical references in this memorandum correspond to the numbering sequence on the respective exhibits.

The modeled hurricane Average Annual Loss by zone in this analysis are developed based on AIR US Hurricane Model v1.0.0 (Florida Regulatory) in Touchstone 2022 with exposures in-force as of June 30, 2022 consistent with the statewide rate level indication. The model was run two separate times to produce output for two scenarios.

- Scenario 1: Coverage C and Coverage A levels left at actual coverage amount purchased by the policyholder.
- Scenario 2: Coverage A Limits set to the Base Limit (30% of Coverage C)

Having the results of these two scenarios allows Castle Key to see how much additional Coverage A losses are created by purchasing additional Coverage A. Modeled hurricane Average Annual Loss for additional Coverage A is calculated as the difference between Scenario 1 losses and Scenario 2 losses. Coverage amounts for additional Coverage A are calculated as the difference between Scenario 1 Coverage A limits and Scenario 2 Coverage A limits. Both calculations are done at the zip level in order to calculate relativities for the territorial analysis.

Please note that data from policies that will be non-renewed has been removed from all calculations.

Territory Support Exhibit 4.1 – Hurricane Coverage A Relativities

(1a) Zip Code

(1b) Wind Peril Zone
Zip codes were grouped into 11 zones for the wind peril. Castle Key is utilizing the Wind Peril Zones as an alternative grouping in this territorial analysis for low exposure zip codes.

(2) Current On-Level Hurricane Additional Coverage A Premium:

These are the aggregate current hurricane Coverage A premiums by zip code. The data is in-force as of October 27, 2022.

(3) Current Additional Coverage A Purchased ($000s)
These are the aggregate current Coverage A amounts purchased by territory. The data is in-force as of October 27, 2022.

(4) Policies in Force (with Additional Coverage A Purchased)
Policies in-force that purchased additional Coverage A as of June 30, 2022. These are the policies that underly the AIR Modeled results.

(5) Current On-Level Average Hurricane Additional Coverage A Premium per $000 of Additional Coverage A:
These are the current average hurricane Coverage A premiums. In parts (5a) & (5b), it is aggregated at a zip and peril zone level. Part (5c) selects which current average premium to use for each zip. Zip-level average hurricane premium is used if a zip group has enough exposures. In cases where there are low exposures in a zip code, the average hurricane premium for the corresponding peril zone is substituted. The criteria used to determine low exposure is less than 15 policies-in-force with additional Coverage A purchased.

The purpose of this information is to capture each zip code's premium differences based on the current hurricane rates. The data is in-force as of October 27, 2022.

(6) Current Additional Coverage A Distribution: (3) / (3) Statewide
The distribution of current Coverage A purchased in each zip code as a percentage of statewide current Coverage A purchased.

(7) Average Hurricane Additional Coverage A Premium Relativities: (5c) / (5c) Statewide
An average hurricane Coverage A premium relativity for each zip code is derived by dividing the selected on-level average hurricane Coverage A premium for each zip code by the statewide average hurricane Coverage A premium.

(8) Standard Model Average Annual Loss (AAL) & LAE (Zip Code):
The Average Annual Loss is the result of the AIR US Hurricane Model v1.0.0 (Florida Regulatory) in Touchstone 2022 with exposures in-force as of June 30, 2022. The AAL is the difference between Scenario 1 and Scenario 2 losses which set Coverage A Limits to the actual limits and the base limit, respectively. The AAL is grossed up by a 20% LAE load as supported in the Indication Filing Memo. The sum of the statewide total of Exhibit 2.2, Column (3) and Exhibit 4.1, Column (8) reconciles to the Projected Hurricane Loss and LAE in column (33) of the RIF.

(9) Additional Coverage A Purchased ($000s) (Zip Code):

Additional Coverage A purchased in-force as of June 30, 2022 from exposures which underly the AIR Modeled results.

(10) Expected Hurricane Coverage A Loss (Zip Code): (3) / (4)
The expected hurricane additional Coverage A loss per $1,000 of additional Coverage A purchased by zip is developed by dividing the modeled hurricane AAL and LAE by the additional Coverage A purchased amounts in force for each zip code.

(11) Standard Model Average Annual Loss (AAL) & LAE (Wind Peril Zone):
Results from column (8) aggregated at the peril zone level.

(12) Additional Coverage A Purchased ($000s) (Wind Peril Zone):
Results from column (9) aggregated at the peril zone level.

(13) Expected Hurricane Coverage A Loss (Wind Peril Zone): (11) / (12)
The expected hurricane additional Coverage A loss per $1,000 of additional Coverage A purchased by peril zone is developed by dividing the modeled hurricane AAL and LAE by the additional Coverage A purchased amounts in force for each peril zone.

(14) Selected Expected Hurricane Coverage A Loss:
If a zip code's number of in-force exposures is greater than or equal to 15, the expected hurricane catastrophe loss for the zip code is selected. However, if a zip code's number of in-force exposures is less than 15, then the expected hurricane catastrophe loss of the corresponding peril zone is selected to mitigate distortions in expected hurricane catastrophe losses for zip code with low exposures. Given that zip codes within each peril zone should have similar hurricane risk, the expected hurricane catastrophe losses for these zip codes should be similar to their corresponding peril zones as well.

(15) Balanced Hurricane Coverage A Loss Relativities: (14) / (14) Statewide
A hurricane Coverage A loss relativity for each zone is derived by dividing the hurricane catastrophe losses for each zip code by the statewide hurricane catastrophe losses. The statewide hurricane Coverage A loss in column (14) is derived by weighting the selected zip code hurricane Coverage A losses with the corresponding current additional Coverage A purchased in column (6). Because of this, the zip code relativities are already balanced so that the statewide relativity is 1.000.

Territory Support Exhibit 4.2 – Hurricane Coverage A Relativity Changes

(1) Zip Code: Same as Exhibit 4.1 Column (1a)

(2) Average Hurricane Additional Coverage A Premium Relativities: Same as Exhibit 4.1 Column (7)

(3) Balanced Hurricane Additional Coverage A Loss Relativities: Same as Exhibit 4.1 Column (15)

(4) Indicated Relativity Change excluding the Offset Factor: (3) / (2) - 1

(5) Proposed Relativity Change excluding the Offset Factor
The proposed hurricane Coverage A relativity changes were targeted to move 50% towards indicated values with a threshold indication of +/- 5% and a capped proposed change of +/- 20%. The relative changes were selected to reflect emerging loss experience while attempting to mitigate policyholder impacts.

(6) Proposed Relativity Change including Offset Factor
The Coverage A relativities account for both the territorial segmentation and the overall rate level. The proposed relativity changes are uniformly adjusted by an offset factor to achieve the targeted rate change to the Hurricane Coverage A Premium.

(7) Current Hurricane Coverage A Rate Per $1,000

(8) Proposed Hurricane Coverage A Rate Per $1,000: (7) * (1 + (6))
The new rates after the proposed relativity changes are applied to current rates.

CERTIFICATE OF TRUE AND ACCURATE RATE FILING

I, Kathryn R Irey, Chief Executive Officer
(Print or type name) (Print or type title)

Section 627.062(8) requires that this form must be signed by either the Chief Executive Officer or Chief Financial Officer, as well as the Chief Actuary.

and

Samantha Steiner Chief Actuary*,
(Print or type name)

pursuant to Section 627.062(8), Florida Statutes, under oath, do swear and attest, based upon the signing officer's and actuary's knowledge, under penalty of perjury, that:

1. We have reviewed the foregoing rate filing;

2. The rate filing does not contain any untrue statement of a material fact, or omit to state a material fact necessary in order to make the statements made, in light of the circumstances under which such statements were made, not misleading;

3. The information contained in the rate filing relating to the factors described in s. 627.062(2)(b), F.S., including, but not limited to, investment income, fairly represents in all material respects the basis of the rate filing for the periods presented in the filing; and

4. The filing reflects all premium savings that are reasonably expected to result from legislative enactments and are in accordance with generally accepted and reasonable actuarial techniques.

(Signature) Chief Executive Officer or (Signature) Chief Financial Officer

Kathryn R Irey
(Print Name)

(Print Name)

Samantha E Steiner
(Signature) Chief Actuary

Samantha Steiner
(Print Name)

* Chief Actuary means an actuary, as defined in Section 627.0645(8), Florida Statutes, that is either employed by the insurer as the Chief Actuary or, if the insurer does not employ a Chief Actuary, is the primary consulting actuary involved in the preparation and review of this rate filing.

OVERALL INSTRUCTIONS

For completing the Rate Indications Forms (RIFs)

(a) This spreadsheet workbook handles any one of the following "Product Types":

HO: Homeowners
MHO: Mobile Homeowners
DF: Dwelling Fire

Before entering anything else, select your "Product Type" in the "Overall Inputs" sheet.

(b) The 10 Rate Indications Forms (RIFs) are exactly the same.

(c) Input cells are shown in connection with the color: BLUE or GREEN
Green input cells are dollar values and must be entered in thousands; blue input cells represent all other inputs.
All cells that are non-blue and non-green cannot be modified by the user.

(d) When entering dollar values in thousands, use rounding, e.g., $123,499 --> $123; $123,500 --> $124

(e) "(SUPPORT!)" appears in color: RED This designator occurs in the following locations:

-- Annual premium trends (in the "Inputs By RIF" sheet)
-- Annual loss trends (in the "Inputs By RIF" sheet)
-- Various items in the 10 RIFs

Whenever the red designator "(SUPPORT!)" appears next to an item, you are REQUIRED to provide for that item a detailed derivation with appropriate supporting data in an uploaded separate document. (Also, whenever dollar amounts are estimated or allocated amounts rather than actual amounts, you are REQUIRED to do the same.)

(f) If you need more than 10 RIFs, use multiple copies of this spreadsheet workbook.

PRODUCT-SPECIFIC INSTRUCTIONS

For completing the Rate Indications Forms (RIFs)

INSTRUCTIONS SPECIFIC TO HO/MHO/DF:

(a) Separate rate level indications and accompanying support on a statewide basis must be provided by program and policy type unless a series of programs and policy types bears uniform statewide factor relationships to each other. For those programs and policy types that do bear uniform statewide factor relationships to each other, combined rate level indications and support for such indications on a statewide basis can be provided along with supporting data for the proposed uniform statewide factor relationships.

(b) Rate level indications and supporting data must be provided for each policy type within a program if rate changes are being requested for one or more of the policy types within the program.

(c) For Dwelling Fire filings, the rate level indications can be shown separately by coverage or the coverages can be combined.

(d) Absent any supporting data/information to the contrary, the OIR will conclude that each rate level indication is included in a range whose maximum is the rate level indication and whose minimum is the rate level indication adjusted to eliminate profit & contingencies and investment income.

(e) If the total "Earned House Years" in item (3) of a RIF is 5,000 or less for all accident years combined:
In the "Inputs By RIF" sheet, specify "Insufficient Data Set" for the RIF
In the "Inputs By RIF" sheet, provide annual premium trend for the RIF (loss trend unnecessary)
In the respective RIF sheet, complete items (3), (4), (5), (6), (9), and (60) only (for item (6), the latest year only will suffice)
NOTE: You may choose to complete the entire RIF if you provide a vaild reason for doing so.

(f) The accident year "ACTUAL INCURRED LOSSES" and "ACTUAL INCURRED ALAE" included in the RIFs must be evaluated at 15, 27, 39, 51, and 63 months of maturity. The accident years used can end on December 31 or any other day of the year.

(g) Partial accident years will not be accepted. A partial accident year is one in which the first policy is not written on or before the first day of the accident year. An immature accident year is one in which the first policy is written less than one year before the first day of the accident year. An insurer is not required to include an immature accident year in the rate indications. If the insurer chooses to include an immature accident year, it should demonstrate that no adjustments are necessary or that appropriate adjustments have been made.

(h) The cost of reinsurance must be included as a "net" expense factor. That is, it must consider the amount to be paid to the reinsurer, expected reinsurance recoveries, ceding commissions to be paid to the insurer by the reinsurer, and other relevant information specifically relating to cost such as a retrospective profit sharing agreement between the insurer and the reinsurer.

(i) If you are not recouping the reimbursement premiums you paid to the Florida Hurricane Catastrophe Fund (FHCF), the cost of reinsurance must include the "FHCF Reins. Cost" and the "Non-FHCF Reins. Cost". Supporting data must be provided separately for each of these elements and the tax-exempt status of the FHCF must be included. Also included in the supporting data must be a chart showing the attachment points of all the various layers of reinsurance including the FHCF reinsurance and support for each attachment point. This chart must clearly demonstrate that other reinsurance does not duplicate the coverage provided by the FHCF.

(j) If you are recouping the reimbursement premiums you paid to the FHCF, the cost of reinsurance must not include the "FHCF Reins.Cost". Also, you must exclude the expected hurricane losses and loss adjustment expenses covered by the FHCF in the calculation of your rate level indications and you must exclude the reimbursement premiums collected from your policyholders in the calculation of your rate level indications. However, you must still provide the expected Hurricane loss and loss adjustment expenses losses covered by the FHCF and the reimbursement premiums you paid to the FHCF along with supporting data for these amounts. Finally, you must still provide a chart showing the attachment points of all the various layers of reinsurance including the FHCF reinsurance and support for each attachment point. This chart must clearly demonstrate that other reinsurance does not duplicate the coverage provided by the FHCF.

(k) The use of contingent commissions as supporting data for rate changes is prohibited unless there is a contractual arrangement between the insurer and its agents concerning the payment of contingent commissions and the insurer demonstrates that it is not paying contingent commissions from profits higher than anticipated in its filings.

(l) All rate level indications included in a filing must comply with the requirements included in this Standardized Rate Indications workbook.

(m) Program name(s) must be consistent with those shown in the Rate Collection System (RCS).

(n) Policy type(s) must include all policy types included in the rate level indication.

(o) Coverage (Dwelling Fire only) must include all coverages included in the rate level indication.

(p) Separately provide the following:

(1) An exhibit that lists your rate level history and includes an explanation of the calculation of the "Current Rate Level Factors"
(2) Supporting data for the selected "Annual Premium Trend"
(3) Your definition of non-hurricane catastrophe losses
(4) An explanation of the derivation of the "INCURRED ULAE" amounts along with supporting Florida data.
(5) Supporting data for the selected "Annual Loss Trend (Up-to-Date)" and the "Annual Loss Trend (Projected)"
(6) Supporting data for the selected "Loss & ALAE Development Factors"
(Include Florida-only historical Loss & ALAE data consistent with the "ACTUAL INCURRED LOSSES Excl. Cats." and the "ACTUAL INCURRED ALAE Excl. Cats." included in the indications)
(7) Detailed supporting data for the "PROJECTED NON-HURR. CAT." amounts
(8) Detailed supporting data for the "Projected HURRICANE Losses, ALAE, and ULAE" amounts.
The "Projected HURRICANE Losses" must be from a model accepted by the Florida Commission on Hurricane Loss Projection Methodology and may not be modified or adjusted.
The date of the policy in-force data (see yellow highlighted cell G51) should be same as the last day of the most recent accident year included on the Rate Indication Form.
If more current data is appropriate, provide it and explain why it is more appropriate.
(9) Supporting data for the "Selected Accident Year Weights"
(10) Supporting data for the selected "Credibility". Note - this Credibility is applied to the sum of the Proj. Incurred Loss & LAE Ratio (Incl. all catastrophes) plus the Expected Fixed Expense Ratio.
(11) Supporting data for the selected "Fixed Expense Loading" by category including the latest three years of historical data if available
(12) Supporting data for the selected "Variable Expense Loading" by category including the latest three years of historical data if available
(13) Supporting data for any "Adjustment Factor for Law Changes, Etc." other than 1.000

(q) The selected "Profit & Contingency" expense loading must be consistent with Rule 69O-170.003, F.A.C.

(r) No expense loadings should be included for Florida Insurance Guaranty Association assessments, Citizens Property Insurance Corporation assessments, Florida Hurricane Catastrophe Fund premium payments, or Managing General Agent fees.

(s) The "Total Expense Loading" by category must be consistent with the expense loadings shown in the Premium Breakdown section of the RCS submission.

OVERALL INPUTS

INFORMATION FOR ALL RIF'S:

Description	Input	Comments
Group Name:	Castle Key Insurance Companies	*Used for exhibit labelling purposes*
Companies within Group (with appropriate abbreviations):	Castle Key Indemnity Company - CKI	*Abbreviations entered here are used only in the "Inputs by RIF" sheet, column (4) for labelling (Should be 2-5 letters for spacing reasons)*
Product Type:	Homeowners	*KEY INPUT -- The three selections are HO, MHO, and DF*
Product Sub-Type:	Condo	*Additional identifier representing the scope of the workbook; used for exhibit labelling purposes (can be blank or N/A)*
State:	Florida Experience Only	*Florida experience required*
Accident Years Ending for RIF's 1 through 10:	6/30/2018 6/30/2019 6/30/2020 6/30/2021 6/30/2022	*Enter as MM/DD/YYYY starting with EARLIEST year.* *If data does not apply for one or more required years (such as if program was not yet begun), the year(s) must be included with zeroes as data. Do not use partial years.*
Loss Experience Evaluation Date:	9/30/2022	*Should generally be a date within the last 6 months*
Assumed Effective Date for New Rates:	5/14/2023	*Should generally be the renewal business effective date*
Frequency of Rate Reviews Assumed -- "A" for Annual; "S" for Semiannual:	A	
Policy Term Assumed -- "A" for Annual; "S" for Semiannual:	A	
Average Accident Date for Proj. Rates:	5/13/2024	*Calculated using the three immediately preceding inputs*
Number of Years of Net Trend Assumed for Recipient of Complement of Credibility:	1.00	*Based upon "Frequency of Rate Reviews Assumed" above*
Exhibit Numbering Label:	STATE EXHIBIT 1	*This label will appear in the upper right hand corner of each exhibit*

STANDARDIZED RATE INDICATIONS

WORKBOOK MEMORANDUM

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM
FLORIDA

SUMMARY OF THE DEVELOPMENT OF STATEWIDE RATE LEVEL INDICATION

The data used in the calculation of the rate level indication was selected in accordance with the considerations listed in Section 3.2 of Actuarial Standard of Practice No. 23, *Data Quality*. The calculation of the rate level indication is consistent with the Statement of Principles Regarding Property and Casualty Insurance Ratemaking.

A rate level indication is a test of the adequacy of expected revenues versus expected costs during the future policy period. Therefore, to derive the indicated rate level need accurately, Castle Key's historical premium and loss experience need to be adjusted. In accordance with Section 3.1 of Actuarial Standard of Practice No. 13, *Trending Procedures in Property/Casualty Insurance Ratemaking,* Castle Key trends the underlying historical experience for premiums and losses to appropriately reflect historical and projected changes in these components of the rate level indications. In addition, historical premiums must be adjusted to reflect the current rate level, and historical losses must be adjusted to reflect expected development over time. All actual catastrophe losses during the experience period were removed and then replaced with a provision to reflect expected catastrophe losses. Details of these necessary adjustments to the historical data used in the rate level indication are described in this memorandum. The adjustments have been applied to Florida’s premium and loss experience in deriving the indicated rate level change.

Attachment B, Exhibit 1 summarizes the indicated rate change and the actual rate level change. The determination of the overall indicated change is included in the Standardized Rate Indications Workbook and is described in detail throughout this filing.

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM
FLORIDA

SUMMARY OF THE DEVELOPMENT OF HURRICANE AND NON-HURRICANE INDICATIONS

The hurricane and non-hurricane indicated change factors are determined by estimating their respective contributions to the overall indicated change factor. They are estimated as follows:

$$\text{Hurricane Indicated Change Factor} = \frac{\text{(Hurricane Costs / Total Premium at CRL) *}}{\text{(Hurricane Premium at CRL / Total Premium at CRL)}}$$

$$\text{Non-Hurricane Indicated Change Factor} = \frac{\text{(Non-Hurricane Costs / Total Premium at CRL) **}}{\text{(Non-Hurricane Premium at CRL / Total Premium at CRL)}}$$

The numerators of these quotients are calculated as follows:

$$* \frac{\text{Projected Hurricane Loss \& LAE Ratio + Reinsurance Costs Ratio}}{\text{1 – Variable Expenses – Profit \& Contingencies}}$$

$$** \frac{\text{Projected Non-Hurricane Loss \& LAE Ratio + Fixed Expense Ratio}}{\text{1 – Variable Expenses – Profit \& Contingencies}}$$

To calculate targeted rate changes, the hurricane and non-hurricane indications are multiplied by an adjustment factor. This adjustment factor accounts for the difference between the total selected change and the total indicated change. Hurricane and non-hurricane targeted rate changes are capped and floored at ±25% if moving in the opposite direction as the total indicated rate change. These targeted changes serve as a starting point for hurricane and non-hurricane selected changes. Slight variations from targeted changes may be needed to achieve the actual rate level change to the nature of the measurement process. In addition, minor updates to the indication may result in differences between calculated targeted changes and actual changes. The selected rate change is broken out by component in **Attachment B, Exhibit 2**.

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM
FLORIDA

BASE DATA IN NON-HURRICANE CALCULATION

In developing rate level indications for Florida, non-hurricane data from fiscal accident years ending June 30, 2020, 2021, and 2022 was considered. Each of these fiscal accident years is evaluated as of September 30, 2022.

All policies that will be non-renewed have been removed from loss and premium data underlying the non-hurricane calculations.

Accident Year Weights

In order to develop a credible measure of the indicated rate level, it is sometimes necessary to use more than one year of historical loss experience. A maximum of five accident years are combined to determine the indicated provision for loss and loss adjustment expense ratio. The number of years used is based upon a credibility procedure from the paper "On the Credibility of the Pure Premium" (Proceedings of the Casualty Actuarial Society, Vol. LV, 1968), by Mayerson, Jones and Bowers.

The analysis was completed using a k value of 0.05 and a P value of 0.90; these parameters reflect the desire that the observed pure premium should be within 100k% of the expected pure premium with probability P. Assuming a Poisson frequency, an empirical review of the severity size of loss curve provides a gauge of credibility based on the number of claims closed with a payment. The applicable weights are shown in **Attachment B, Exhibit 8.**

This approach for incorporating credibility in determination of the accident year weights is consistent with the Current Practices and Alternatives detailed in Section 3 of Actuarial Standard of Practice No. 25, *Credibility Procedures Applicable to Accident and Health, Group Term Life, and Property/Casualty Coverages*.

Credibility

The available accident year data used in the indication is not fully credible. Therefore, we determine the partial credibility of the accident year data using the credibility procedure referenced in the Accident Year Weights section above. The partially credible rate level indication using the accident year data is then weighted with the expected annual net trend, as shown in **RIF1**, to produce the credibility-weighted rate level indication.

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM
FLORIDA

BASE DATA IN HURRICANE CALCULATION

The modeled hurricane Average Annual Loss is based on AIR US Hurricane Model v1.0.0 (Florida Regulatory) in Touchstone 2022 with exposures in-force as of June 30, 2022. The Product Instructions of the Standardized Rate Indications workbook state that the policy in-force date should be the same as the last day of the most recent accident year included in the rate level indication, or more recent if appropriate. Our internal catastrophe modeling partners produce modeled runs twice per year based on June 30 and December 31 exposures. Since the rate level indication in this filing uses data ending June 30, 2022 the modeled results based on June 30, 2022 are utilized to comply with this rule.

All policies that will be non-renewed have been removed from in-force exposures underlying the modeled hurricane Average Annual Loss.

No other adjustments are made to the expected modeled losses. The calculation of the appropriate hurricane provision is described on **Page 17** of this memo. Premium adjustments to the in-force premium and policy count are detailed on **Page 6** of this memo.

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM
FLORIDA

ADJUSTMENTS TO PREMIUMS IN NON-HURRICANE CALCULATION

Current Rate Level

Earned Premiums in the experience period were adjusted to current rate level using the parallelogram method. The parallelogram method is also used to bring premiums to current rate level prior to calculating the changes in average premium (the premium trends). The historical rate changes and factors to current rate level are provided in **Attachment B, Exhibit 3**.

Premium Trend

In addition to bringing premiums to current rate level, changes in the average written premium at the current premium level were reviewed. Based upon this review, a premium trend of -3.0% was selected to account for shifts in the distribution of various underlying factors that are inherent in a rapidly growing book of business. Selected trends are based on Castle Key Indemnity Company historical data provided in **Attachment C, Exhibit 4**.

Please note that the premium trends are based on average premium and as such incorporate Amount of Insurance (AIY) as well as other rating plan distribution shifts. The purpose of the premium trend is to account for shifts in the distribution of various underlying rating factors. As the effects on losses caused by these shifts are reflected in the loss trends, it is important that Castle Key accounts for the anticipated future change in premiums. AIY is only one factor that determines a policy's premium. Because of this, Castle Key believes it is appropriate to use historical average written premium data in order to select premium trends. Castle Key is not aware of any one-time events that would have affected the more recent time period that was used as the basis for its premium trend selections. Therefore, Castle Key believes that reflecting the natural historical distribution shift on an on-going basis is appropriate.

Please note that all policies that will be non-renewed have been removed from the premium trend data.

ADJUSTMENTS TO PREMIUMS IN HURRICANE CALCULATION

In-Force Data

Castle Key is using an in-force snapshot that aligns to the date of the exposures underlying the hurricane model run. All policies that will be non-renewed have been removed from the in-force premium data.

Current Rate Level

Premiums were adjusted to current rate level using the parallelogram method. There is no premium trend applied in the hurricane calculation.

The premium adjustments in the hurricane calculation are detailed in **Attachment B, Exhibit 7**.

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM
FLORIDA

ADJUSTMENTS TO LOSSES IN NON-HURRICANE CALCULATION

Loss Development

Consistent with previous filings in the Castle Key Insurance Company condominium program, Castle Key has selected ultimate accident year losses (including allocated loss adjustment expense) after analyzing ultimate incurred loss estimates arising from two loss development methods: the link ratio method and the additive method. Due to the limited loss experience available in Castle Key Indemnity Company, Castle Key is utilizing Castle Key Insurance Company condominium losses to calculate loss development factors. Castle Key expects losses to develop similarly in both companies.

To calculate estimated ultimate losses using the link ratio method, historical age-to-age link ratios are calculated, which represent loss development between different evaluation periods. An average of the historical link ratios is then used to estimate the ultimate level of paid losses to be used in ratemaking. This method assumes that historical loss development patterns can be used to estimate future loss development on current immature claims.

For the additive loss development method, historical losses are first trended to today's price level using selected pure premium trends from Castle Key Insurance Company data. This is done to avoid distortions due to changes in the underlying loss costs. Trended additive amounts per exposures are calculated, which represent trended loss development between different evaluation periods. An average of the historical trended additive amount per exposure is then used to estimate the ultimate trended level of paid losses. Trended age-to-ultimate additive amounts per exposure are multiplied by earned exposures for each accident year to calculate trended losses that have yet to emerge. A final step in the additive method is to detrend the trended losses yet to emerge. Losses are detrended because the application of trend is accounted for in a separate step in the ratemaking process. This method assumes that historical loss development patterns per exposure can be used to estimate future loss development on current immature claims.

Refer to **Attachment B, Exhibit 10** for the loss development using both the link ratio and additive methods of loss development. The data shown in the exhibit are non-catastrophe losses including sinkhole. Sinkhole data is included in loss development because sinkholes are included in the underlying data to which loss development factors are applied. **Attachment B, Exhibit 10.1** displays data from Castle Key Insurance Company's Condominium business, which is used to select loss development factors in this indication. **Attachment B, Exhibit 10.2** displays data from Castle Key Indemnity Company. This data is provided for transparency, but it was not utilized to select factors as the book of business is too new. A summary of the estimated ultimate losses using each method as well as the selected ultimate losses is shown on **Attachment B, Exhibit 9**. Please note that 5-year average loss development factors and additive amounts per exposure were used for all maturities.

Loss Adjustment Expenses

Allocated loss adjustment expense (ALAE) is included in the losses. Losses in the experience period have been adjusted to account for non-hurricane unallocated loss adjustment expenses (ULAE). A provision is developed considering Florida-specific Castle Key Insurance Companies data and Countrywide Allstate Insurance Group Data. A three-year average of the ratios of calendar year non-hurricane ULAE to calendar year non-hurricane incurred losses and allocated loss adjustment expense is used to determine the ULAE provision. The average ratio is then applied to the losses for each year used in the formula calculation. Castle Key has selected the ULAE provision utilizing Florida Data. The ULAE ratio used in this filing is shown in **Attachment D, Exhibit 1**.

Loss Trend

Due to the limited and volatile loss experience available in Castle Key Indemnity Company, data from Castle Key Insurance Company has been included to inform trend selections.

Using Castle Key non-catastrophe data for the state of Florida, the past changes in actual frequency and severity on a twelve-month-moving basis (evaluated at each quarter) over a 5-year period were examined. After considering past results and actuarial judgment, annual pure premium trends were selected. The Castle Key data has been adjusted as described below.

Frequency and severity amounts are calculated using the methodology in "The Effect of Changing Exposure Levels on Calendar Year Loss Trends" (Casualty Actuarial Society Forum, Winter 2005) by Chris Styrsky. This methodology helps to more consistently match losses and claims paid with the exposures that produced the claims.

Castle Key is including ALAE in the loss trend calculations since the trend factors are applied to both loss and ALAE in the indication.

The positive loss trend selection of 9% is being driven by a positive long-term severity trend. Water, which is the largest peril for the Condominium line, is the primary cause of this long-term positive trend.

This approach for selecting pure premium trends and projections is consistent with the Current Practices and Alternatives detailed in Appendix 1 – Background and Current Practices of Actuarial Standards of Practice No. 13, *Trending Procedures in Property/Casualty Insurance Ratemaking*. The selected trends are displayed in the Standardized Rate Indications Workbook**.** These annual selections are used to project the data from the average occurrence date of the experience period to the average occurrence date of the future policy period. The projection is also shown in the Standardized Rate Indications Workbook. Castle Key frequency, severity, and pure premium trend data are included in **Attachment C**.

Non-Modeled, Non-Hurricane Catastrophes

Castle Key separately identifies and accounts for its exposure to loss due to the occurrence of catastrophic events within a state. All actual catastrophe losses during the experience period were removed and then replaced with a provision to reflect expected non-hurricane catastrophe losses

in Florida. The non-modeled, non-hurricane catastrophe provision is described in detail on **Page 15**.

Please note that in developing the Expected Non-Hurricane Catastrophe Loss and LAE, the Amount of Insurance Years (AIY's) are used as an exposure base. One AIY is equal to $1,000 of Coverage in force for one year. The AIY's must be adjusted to represent the AIY's that we expect to be in force during the policy period. Selections are based on Castle Key Indemnity Company data. **Attachment C, Exhibit 5** shows the AIY trends for Florida. A -1% provision to project the AIY's to the average earned date of the proposed policy period has been selected.

Data for policies that will be non-renewed has been removed from the AIY trend calculations.

This approach for selecting AIY projections is consistent with the Current Practices and Alternatives detailed in Appendix 1 – Background and Current Practices of Actuarial Standards of Practice No. 13, *Trending Procedures in Property/Casualty Insurance Ratemaking.*

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM
FLORIDA

EXPENSES, PROFIT PROVISION & CONTINGENCY FACTOR

The expense provisions described below were derived in accordance to Section 3.2, Determining Expense Provisions, of Actuarial Standard of Practice No 29, *Expense Provisions in Property/Casualty Insurance Ratemaking*.

The Standardized Rate Indications Workbook shows the expense provisions used in developing the current fixed and variable expense ratios, as well as the underwriting profit and contingency provisions.

Fixed Expenses

General and Other Acquisition Expense

The provisions for general expense and other acquisition expense are based on Castle Key specific data since Castle Key specific general expense data has been relatively stable over time. To develop the provision for other acquisition and general expenses, a three-year average of calendar year incurred expense divided by calendar year direct earned premium was calculated. The expense figures are derived from the Insurance Expense Exhibit. The provision for other acquisition expense has been reduced by the amount of installment fees collected. In addition, the provision has been adjusted for premiums written off. The provisions for Countrywide and Florida-specific data are shown on **Attachment D, Exhibit 2**.

The other acquisition expense provision provided in the filing includes more than just expense incurred in acquiring new business. It also includes servicing and other administrative expenses that are expected to continue after the initial policy period in which the new business policy was acquired. As such, Castle Key believes the other acquisition expense provision included in the filing is appropriate.

Licenses & Fees

A provision for licenses and fees that do not vary by premium size is determined by taking the arithmetic average ratio of these licenses and fees from the latest three calendar years in Florida. The provision for licenses and fees is considered, along with the general and other acquisition expense provisions, to be a fixed expense and is shown on **Attachment D, Exhibit 5**.

Net Cost of Reinsurance (NCOR)

Given the planned non-renewal actions in CKI Condo, Castle Key asked our reinsurance intermediary, Aon Reinsurance Solutions, to restate the 2022-23 reinsurance program as if the policies that will be non-renewed were not in our book of business as of September 30, 2022, while retaining all other in force policies as of that date. Relying on their reinsurance market knowledge, Aon adjusted the 2022-23 reinsurance contracts and provided revised reinsurance premiums and expected recoveries. This new scenario is referred to as the “As-If” scenario. **Attachment D, Exhibit 7** provides a side-by-side view of the reinsurance chart for the original, previously filed, 2022-23 reinsurance program based on projected exposures, and the new 2022-

23 as-if Scenario based on actual exposures. The as-if scenario has a smaller Below FHCF (Florida Hurricane Catastrophe Fund) layer, a smaller Second Excess Layer, and has no Third Excess Layer. The CKI FHCF Layer is smaller to reflect the reduced condo exposures. The CKIC FHCF layer is slightly different in the as-if scenario only because it is based on actual exposures instead of the original projected exposures. Note that the FHCF layering is determined based on either projected or actual exposures as of June 30, 2022 depending on the scenario, as further detailed later in this memo. The Annual Aggregate Contract layering is the same as the original scenario.

Attachment D, Exhibit 6, Pages 1 and 2 include the calculation used to develop the FHCF and non-FHCF reinsurance expense ratios, based on the FHCF and non-FHCF reinsurance premium and expected loss savings associated with Castle Key Insurance Group's 2022-2023 as-if scenario.

The net cost of reinsurance is calculated as the difference between the amount paid to the reinsurer/intermediary and the expected reinsurance recoveries. Castle Key is proposing to incorporate expected recoveries based on AIR US Hurricane Model v1.0.0 (Florida Regulatory) in Touchstone 2022 into the NCOR calculations. The expected recoveries are based on September 30, 2022 actual exposures, less the planned non-renewals.

The reinsurance recoveries reflect ceded LAE. LAE is applied to any potential recoveries as stipulated within the contract provisions. The reinsurance premium and recoveries also reflect reinstatement premium/reinstated events.

The non-FHCF net reinsurance premium (removing reinsurance intermediary's premium adjustment for expense reduction) is proportioned to line and company by expected recoveries as determined by AIR Model v1.0.0 since Castle Key's non-FHCF reinsurance contracts are written on a joint basis for Castle Key Insurance Company and Castle Key Indemnity Company. The regular FHCF adjusted reinsurance premium (including a cash build-up for 2022-23 contract year, according to section 215.555(5) (b) of the Florida Statutes), is proportioned only to line by expected recoveries as determined by the AIR Model v1.0.0.

Because the expected recoveries are based on September 30, 2022 actual exposures, less the planned non-renewals, the denominator of the NCOR provision is the September 30, 2022 actual written premium at current rate level, adjusted for the planned non renewals. This premium is included on **Attachment D, Exhibit 6, Page 3**.

Attachment D, Exhibit 6, Page 4 provides a comparison of Reinsurance Premium and Expected Recoveries between the actual program and the as-if program.

Castle Key's actual June 30, 2022 exposures were run through a FHCF calculator to determine the FHCF retention, exhaustion, and premium. This process is completed by our reinsurance intermediary, Aon Reinsurance Solutions. The values in the as-if scenario are based on the final FHCF layer for CKIC. The CKI values are adjusted based on the planned non-renewals.

The majority of the reinsurance program for Castle Key is constructed of per-occurrence contracts. These per-occurrence contracts inure to the benefit of an annual aggregate contract.

The structure of the program including per-occurrence and annual aggregate features is detailed further in **Attachment D, Exhibit 7**. Each event within a given model year is compared to the terms of any applicable reinsurance contracts or catastrophe bonds. For the Excess Contract, FHCF, Catastrophe Bond, and Aggregate Contract, there are no reinstatements of limits available; however, the Below FHCF Layer contract allows for two reinstatements. The first reinstatement of limits is prepaid and the second or final reinstatement requires additional premium. Therefore, reinstatement premium is only considered/reflected when any portion of the second Below FHCF limit is eroded. For purposes of this filing, there are a total of 2,380 years out of the 100,000 modeled which result in a reinstatement premium of any amount being considered.

Variable Expenses

Commission and Brokerage Expense

The proposed commission and brokerage expense provision is the commission and brokerage incurred expense ratio in Florida for the latest year ending December 31, 2021. Please note that the proposed commission is not contingent upon Castle Key Insurance Companies' overall profitability in Florida. The provision is shown on **Attachment D, Exhibit 3**.

The expected commission expense provisions reflected in the indications for both Castle Key, as well as recent Allstate private passenger auto filings are based on actual commissions paid and expected to be paid in the future, which are pursuant to the commission schedules in the agency contracts.

Taxes

The provision for taxes is determined by taking the currently prescribed Florida premium tax ratio and adding fire tax, less tax credits. The provision is shown on **Attachment D, Exhibit 4**.

Debt Provision

Debt is one of the main ways Castle Key raises capital to fund ongoing corporate operations, as well as improve the business. The debt provision represents the cost of debt, or expected, quantifiable future interest payments to bondholders. The provision is shown on **Attachment D, Exhibit 9**.

Technically speaking, for Allstate Corporation, debt is issued only by Allstate Insurance Company, but it is used to fund the actions of Allstate at the corporate level rather than a specific state or line of business. Thus, the entirety of Allstate Corporation benefits from it. As a result, a portion of the cost of debt must be allocated to each business unit. This allocation is applied using the distribution of GAAP equity across Allstate's business units.

One service Allstate Corporation renders to policyholders is assurance that future insured losses will be paid, a promise that is backed by capital. By allocating debt based on equity, each insured pays the same weighted average cost of capital. Thus, Castle Key believes that debt allocation based on equity is equitable and commensurate with services rendered to policyholders.

Underwriting Profit and Contingency Provision

Castle Key has calculated a provision for the underwriting profit using its methodology as well as methodology outlined in Florida Administrative Code Rule 69O-170.003.

Castle Key has performed two separate cost of capital analyses in the estimation of its cost of equity using Allstate Corporation data. The first uses the Fama-French Three-factor Model (FF3F), which reflects developments in the field of financial economics as published in the *Casualty Actuarial Society Forum, Winter, 2004 and in Journal of Risk and Insurance, Vol. 72, No. 3, September 2005* ("Estimating the Cost of Equity Capital For Property-Liability Insurers" by J. David Cummins and Richard D. Phillips). The second is a Discounted Cash Flow (DCF) analysis, which estimates the expected future cash flows to investors in order to gauge the proper cost of equity. Consistent with the previous filing, Castle Key has selected a cost of equity of 11.5%.

Allstate utilizes both the Fama-French model and the Discounted Cash Flow model to leverage the strengths of each model. By incorporating the results of both analyses, Allstate can produce an estimated cost of capital that strikes a balance between the more responsive model and the more stable one. The Fama-French and Discounted Cash Flow analyses are shown in **Appendix 1 and 2** of **Attachment F**.

Please note that Allstate has established a beta-estimation regression model. In 2015, Allstate completed an analysis that used historical monthly stock returns to test the predictive power of various regression methodologies. In the analysis, each methodology was tested for every company in the market portfolio at multiple time periods, and the predicted return (relative to the market return) was compared to the actual return. Based on the average absolute error for the prediction, across the almost one million testing records, we can see which methodologies, on average, are more accurate in the predicted risk premiums. In addition to desiring accuracy, stability is also desired in ratemaking. Therefore, the analysis also tested the average change in calculated betas from one year to the next. The best overall methodology, therefore, would be the one with the optimal combination of accuracy and stability.

An analysis of premium, loss and expense cash flows is used to calculate the investment income on policyholder supplied funds (PHSF). This methodology is one of the two examples given in Actuarial Standard of Practice, No. 30, *Treatment of Profit and Contingency Provisions and the Cost of Capital in Property/Casualty Insurance Ratemaking*, as appropriate methods for recognizing investment income from insurance operations (**page 4**).

The expected investment yield rate (applied as a force of interest) used to discount losses and expenses includes anticipated net investment income and anticipated capital gains, both realized and unrealized. Operating cash flows are discounted to the average time of earnings of premium and profit for the policy year, rather than to the start of the policy year.

Consistent with Rule 69O-170 of the Florida Administrative Code, Castle Key has also calculated an expected investment income yield on invested assets adjusted for capital gains, adjusted Y_A, and a resulting profit allowance of 1.7%; support is provided in **Attachment E**.

However, Subsection (3) of this rule allows for other procedures in the calculation of the underwriting profit, as the promulgated methodology is inappropriate in providing adequate return for the assumed underwriting risk. Specifically, the 3.1% cost of equity resulting from the 1.7% profit allowance, as shown in **Attachment E, Exhibit 6**, is lower than Castle Key's required cost of equity, based on the analysis documented above.

Further, Castle Key is incorporating a 2.0% contingency provision as a variable expense. Please see **Pages 26 to 28** for further explanation. Combining the selected underwriting profit provision at present value of 10.0% and the contingency factor of 2.0% (supported in **Attachment D, Exhibit 8**), a total factor of 12.0% is calculated. **Attachment B, Exhibit 12** displays the total required profit and contingency factor.

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM
FLORIDA

SUMMARY OF THE TOTAL NON-MODELED, NON-HURRICANE CATASTROPHE ADJUSTMENT

Castle Key separately identifies and accounts for its exposure to loss due to the occurrence of catastrophic events within a state. The adjustment to account for non-modeled catastrophes described below is consistent with the Analysis of Issues and Recommended Practices detailed in Section 3.4 of Actuarial Standards of Practice No. 39, *Treatment of Catastrophe Losses in Property/Casualty Insurance Ratemaking*.

Castle Key defines a catastrophe as an event which experiences one or more of the following conditions (earthquakes, firestorm/wildfires, tornadoes, hailstorms, hurricanes, tropical storms, winds, winter events) and has multiple policies with losses, which exceed one million dollars in aggregate. The non-hurricane catastrophe provision excludes modeled hurricane losses.

An estimation of our non-hurricane catastrophe exposure is first developed on a statewide level for Castle Key Insurance Companies. Subsequent relativities are used to estimate our catastrophe exposure by line.

In order to estimate our non-hurricane catastrophe exposure at a statewide level, we develop a long-term relativity of Florida to our countrywide catastrophe factor for the latest fifteen years of data. We then apply this relativity to a countrywide catastrophe factor based on the most recent ten calendar years of data ending December 31, 2021. The countrywide catastrophe factor is shown on **Attachment G, Exhibit 2**. By using this approach, we can balance the stability of a long-term estimate of catastrophe potential in Florida (needed because of the infrequent occurrence of catastrophes) and the responsiveness of more recent data (needed because of changing demographic conditions). **Attachment G, Exhibit 1** displays the Development of the Total non-hurricane catastrophe provision of 0.25.

This total non-hurricane catastrophe provision is then adjusted to account for the difference in the average catastrophe ratio between Owners, Renters and Condominium. **Attachment G, Exhibit 3** displays the development of the Castle Key Insurance Company and Castle Key Indemnity Company line-specific (Owners, Renters, Condo) non-hurricane catastrophe provision. Castle Key Insurance Companies Homeowner data is used to develop a non-hurricane catastrophe provision for the state. Line specific loss data is used to develop catastrophe ratio relativities by line. These relativities are then re-indexed using the most recent year's AIYs and then are applied to the state-specific non-hurricane catastrophe provision for each line.

This line specific provision is the final non-hurricane Catastrophe provision per AIY used in the Development of the Expected Non-Hurricane Catastrophe Loss and Loss Adjustment Expense shown on **Attachment B, Exhibit 6**.

The calculations of the non-hurricane catastrophe provision has not been adjusted to remove the planned non-renewals. The provision is calculated using data from 15 historical years. Given that CKI Condo opened in 2020, the impact of CKI Condo is minimal. Additionally, we are assuming that the selection of non-renewal policies is not heavily correlated with the amount of non-hurricane catastrophe loss. While the calculation of the non-hurricane catastrophe provision has not been adjusted, it is applied to non-catastrophe losses that have non-renewals removed.

CONDOMINIUM
FLORIDA

DEVELOPMENT OF THE HURRICANE PROVISION
BASED ON THE AIR WORLDWIDE TOUCHSTONE 2022 US HURRICANE MODEL VERSION 1.0.0 (FL REGULATORY) IN THE STATEWIDE RATE LEVEL INDICATION

I. INTRODUCTION

The Casualty Actuarial Society Statement of Principles Regarding Property and Casualty Ratemaking defines a rate as "…an estimate of the expected value of future costs" and further states that "a rate provides for all costs associated with the transfer of risk". Rates are therefore an estimate of the costs for the policies to which the rates will apply. In our property ratemaking we assume that the proposed rates will apply to the policies written for one year from the effective date of the rates. Each provision of the rate is based on an estimate of the costs associated with those policies.

Losses expected from a hurricane are significantly different than losses expected from other types of loss events. Hurricanes are unique because of the large potential impact such storms can have on the company's solvency and because of the relatively low frequency of such events.

The significant variation in the frequency of different magnitudes of hurricanes diminishes the accuracy of historical hurricane loss experience for projecting expected loss levels for the policies to which proposed rates will apply. Average expected recurrence periods for the larger, more severe storms are so long that many external variables will change in the time periods between occurrences. For example, the area of southern Florida hit by Hurricane Andrew in 1992 was last hit by a major hurricane, Hurricane Betsy, in 1965. The type, number, value, vulnerability and geographical distribution of exposed properties in the area impacted by Hurricane Andrew are very different than those of the exposed properties in 1965. Actual loss statistics from a hurricane that occurred many years ago are not easily adjusted for the type, number, value, and vulnerability of present day structures.

Since historical hurricane losses cannot be used to accurately estimate current hurricane loss potential, Castle Key has contracted with an outside vendor, AIR Worldwide (AIR), which uses an alternative methodology based on Monte Carlo simulation to arrive at Castle Key's expected annual hurricane losses. This approach involves the development of computer programs that describe in detail the frequency of hurricanes, their meteorological characteristics, and their effects on exposed properties. A high-speed computer then simulates a large set of hypothetical hurricanes and estimates the resulting property losses based on Castle Key's exposure.

In order to estimate the potential loss from hurricanes, 100,000 scenario years of potential hurricanes are simulated. This large number of simulations attempts to ensure that the resulting probability distribution of losses converges to a stable representative distribution of potential annual hurricane loss.

The pattern of simulated hurricanes is representative of what has occurred historically because meteorological data on the actual events since 1900 were used to estimate the parameters of the AIR hurricane simulation model. The meteorological sources used to develop the model are the most complete and accurate databases available from various agencies of the National Weather Service and the National Oceanic and Atmospheric Administration (NOAA), including the National Hurricane Center.

This explanatory memorandum incorporates text taken directly from documents supplied to Castle Key by AIR and should not be copied or distributed without the express, written permission of AIR.

II. HURRICANE PARAMETERS AND WIND SPEED ESTIMATION

HURRICANE PARAMETERS

The key parameters of hurricanes used to simulate each storm and resulting wind speeds are:

1. Hurricane Frequency
2. Landfall Location
3. Central Pressure
4. Radius of Maximum Winds
5. Forward Speed
6. Track Angle at Landfall
7. Storm Track
8. Peak Weighting Factor (PWF)
9. Gradient Wind Reduction Factor (GWRF)

The probability distributions for several of these variables (2-6) are estimated for coastal segments of equal length from Texas to Maine. Random samples are generated from the probability distributions of these input variables to assign values to the variables for each simulated hurricane.

1. Hurricane Frequency

   More than one hundred years of history, spanning the period 1900-2018, were used to estimate the parameters of the annual frequency distribution.

2. Landfall Location

   There are 62 segments of fifty nautical miles in the AIR hurricane simulation model, totaling 3,100 nautical miles of smoothed coastline. Of these, segment 29 in Southern Florida is split into two parts, one of which represents Key West in Florida. Historical landfalls are tabulated by the 62 segments and the frequencies are then smoothed to produce an estimate of the landfall probability for each segment. A cumulative probability distribution of landfall locations is developed for the entire coastline. Once a

landfall segment has been selected from this distribution, the exact landfall location is selected from a uniform distribution within the segment.

3. Central Pressure

Central pressure is the lowest sea-level pressure at the center of the hurricane. This variable is the primary determinant of hurricane wind speed. All else being equal, wind speeds increase as the central pressure decreases, or more precisely, as the difference between the central pressure and the peripheral pressure increases. Distributions are first fitted to historical central pressure data for each coastal segment. Separate distributions are then estimated for larger regions defined based on broad meteorological differences. The final distribution used for each segment is a mixture, with appropriate weights applied, of the regional distributions and the segment distribution.

4. Radius of Maximum Winds

Radius of Maximum Winds (R_{max}) is the distance from the storm's center (eye) to the point where the highest cyclonic wind speeds occur. The R_{max} of stochastic events is estimated using a procedure that relates the R_{max} to the central pressure of the storm and to latitude. The R_{max} is allowed to vary after landfall over the life of the storm.

5. Forward Speed

Forward Speed is the speed at which a hurricane moves from point to point. The parameters of the distribution of forward speed at landfall are estimated for each coastal segment. The lower bound of the distribution of forward speed is three nautical miles per hour. The upper bound is dependent on latitude. Forward speed is allowed to vary after landfall based on historical distributions.

6. Track Angle at Landfall

Landfall angle is measured clockwise (+) or counterclockwise (-) with 0 representing due North. Separate distributions for track angle/storm heading at landfall are estimated for segments of coastline that have variable orientation.

7. Storm Track

AIR's storm track generation procedure is based on historical storm tracks in the HURDAT database. The track information in this database is available at six-hour time intervals. Time series techniques have been used to determine the dependence structure present in key model variables from one time period to the next. Time series models that describe the dependence in the historical data are used in the generation of simulated tracks. For example, a first-order Markov model with transition probabilities estimated from the historical data is used to generate changes in track direction of simulated storms. The storm tracks generated using

this approach are realistic and resemble storm tracks that have been observed for historical storms.

8. Peak Weighting Factor (PWF)

The PWF is a stochastic parameter used to reflect the vertical slant of the hurricane eye. The PWF and GWRF are generated jointly using a bounded Bivariate Normal distribution.

9. Gradient Wind Reduction Factor (GWRF)

The model uses a gradient wind reduction factor to translate calculated maximum wind speeds at upper altitudes of the event to surface wind speeds, defined as 10 meters above the ground. This factor is calculated using the distance from the eye and the PWF.

HURRICANE WIND SPEED ESTIMATION

Once the key parameters have been generated, the meteorological relationships among them are used to develop a complete time profile of wind speeds for each location affected by the storm. This involves the following calculations for each simulated hurricane:

1. Gradient-Level Wind Speed
2. Adjustment to surface (10-meter) level
3. Asymmetry Effect
4. Storm Decay (Filling Effect)
5. Relative Wind Speeds
6. Adjustment of Wind Speed for Surface Friction and Averaging Time

1. Gradient-Level Wind Speed

A maximum upper-level (or gradient-level) wind speed is determined based on central and peripheral pressures, as well as radius of maximum winds and latitude coordinates. The upper level wind is then determined above the location of interest by adjusting the maximum value based on the distance of location from the eye of the storm. This is done using an expected radial gradient wind profile derived from the scientific literature. This wind, called the gradient-level wind speed, is estimated over a 10-minute averaging time.

2. Adjustment to surface (10-meter) level

The gradient-level wind is then reduced to a 10-meter height level through application of a scaling factor and a spatial relationship adjustment. The gradient-wind adjustment factor (GWRF) that is used is a variable factor that represents the observed relationship between gradient-level winds and those measured at a 10-m height. The spatial adjustment accounts for differences in the GWRF relationship between the core and the

periphery of the storm. The resulting wind represents the surface-level (10-meter) wind speed over an open water surface.

3. Asymmetry Effect

   Because hurricanes rotate counterclockwise in the Northern Hemisphere, the combined effects of forward motion and rotational effects on wind direction produce higher wind speeds on the right side of the storm than the left, as viewed facing the storm's forward direction. This phenomenon is captured in the model using the interaction of forward and rotational speeds.

4. Storm Decay (Filling Effect)

   Once over land, the hurricane moves away from its source of energy, i.e., warm ocean water. Central pressure rises and as a result, the eye "fills" and winds degrade. Filling equations used in the AIR model estimate the reduction in over-land wind speed as a function of time since landfall, rather than distance. A fast moving storm can produce damaging winds further inland than a slow moving storm with the same landfall intensity (wind speed). Some storms can also re-intensify after landfall, in accordance with historical data, but central pressure cannot be lower than the central pressure at landfall. The filling equations vary by coastal region and smoothing is performed to ensure that there are no unrealistic jumps between regions.

5. Relative Wind Speeds

   The estimated wind speed at any point within the model domain is dependent on the radius of maximum winds (R_{max}), the distance between the eye of the storm and the location in question, the translational factor between upper-level winds and surface-level wind speeds, and the vertical slant in the eye of a hurricane. As a particular location lies farther from the eyewall, the winds decay until they reach an ambient level at the periphery of the storm.

6. Adjustment of Wind Speeds for Surface Friction and Averaging Time

   Differences in surface terrain also affect wind speeds. The roughness of the underlying surface induces friction which tends to slow down the winds, and induces turbulence effects which tend to generate short-lived gusts. The friction and gust effects are estimated based on the roughness of the surface over which the wind passes and from which direction the winds are coming.

   A friction factor is calculated to capture surface roughness at each affected site and the associated decrease in wind speed that results from surface obstacles. Estimates of surface roughness are derived from digital US Geological Survey (USGS) land use/land cover data. Each terrain type has a different "roughness value" that will lead to different frictional effects on wind speeds at different locations. In general, the rougher the terrain is the larger the effect of friction on wind speeds will be.

Additionally, an adjustment is made to modeled wind speeds near the coast to account for the interaction between wind speed and wave height.

As soon as a storm crosses the coastline, there is an immediate reduction in wind speed. The reduction factors reach equilibrium values when the terrain is homogeneous over sufficiently large areas such that the surface winds come in balance with the surface. Thus, most local variability occurs when the underlying surface is diverse.

A gust factor is calculated to capture the effects of surface turbulence and is also associated with the roughness of the terrain. Smooth surfaces impart only a small turbulent effect. The adjustment for rougher surfaces is more substantial since rough surfaces tend to generate short-lived gusts which will translate to a stronger maximum 1-minute sustained wind speed. The gust factor is computed using the same USGS land use data set as is used for the friction calculation. The final adjusted wind represents a 1-minute sustained wind at a 10-meter height that accounts for the impacts of the local environment and the forward motion of the storm.

III. DAMAGE ESTIMATION AND DEMAND SURGE

AIR engineers have developed damage functions that describe the interaction between buildings, (including both structural and nonstructural components) and their contents, and the local wind speeds to which they are exposed. These functions estimate a mean damage level as well as the variability of damage to wind speed at each location. Because different structural types will experience different degrees of damage, the damage functions vary according to construction class, occupancy, height, etc. The model estimates a complete distribution around the mean level of damage for each local wind speed and each structural type. Losses are calculated by applying the appropriate damage function to the replacement value of the insured property.

The AIR damage functions capture the effects of wind duration as well as the effect of peak wind speed. The longer a property experiences severe wind speeds, the greater the damage. The hurricane damageability relationships incorporate well-documented engineering studies published by wind engineers and other experts outside of AIR. They also incorporate the results of post-hurricane field surveys performed by AIR engineers. These relationships are continually refined and validated based on actual client companies' loss data.

Any major hurricane event causes an increase in demand for materials and services to repair and rebuild damaged property. This can put pressure on costs, resulting in higher than expected costs. Therefore, AIR applies aggregate Demand Surge functions to loss estimates to take into account the combined effects of events clustered in both time and geography.

.

IV. LOSS CALCULATION

CASTLE KEY EXPOSURE DETAIL

Castle Key used detailed policy-level exposure detail. The exposures represent policies in-force as of June 30, 2022, and contain policy-level location information, property characteristics, deductible information, and coverage information. Planned non-renewal policies have been removed from the data.

MODELED LOSS ESTIMATES

Losses estimated from 100,000 years of simulated potential hurricanes are summed and divided by 100,000 to produce the expected annual losses from all hurricanes for each property. Property loss estimates are then aggregated to produce expected annual loss for the state, line, and company.

The total modeled Average Annual Loss for Castle Key Indemnity Company Condominium is divided by premium at current rate level to produce the projected hurricane loss and LAE ratio in the Standardized Rate Indications Workbook. The calculation is shown in **Attachment B, Exhibit 7**.

ADJUSTMENTS TO MODELED LOSS ESTIMATES

As advances in science and changes in claim payment behaviors evolve, Castle Key re-evaluates how it currently reflects modeled hurricane losses in ratemaking. At times it is necessary to adjust the modeled losses to more accurately estimate the Property and Casualty industry's risk from hurricanes. Note that all adjustments made to the modeled losses are under continual development and may change in the future as Castle Key learns more about the changing risk environment. Modeled loss estimates include adjustments for:

- Loss Adjustment Expenses

Loss Adjustment Expenses

Loss Adjustment Expense (LAE), both allocated and unallocated, represents the cost of adjusting, investigating, and settling losses due to the hurricane peril. Allocated expenses are incurred while investigating and settling claims and are considered allocated because they can be linked directly to a claim file. Unallocated expenses are associated with processing claims, but cannot be linked directly to a claim file. Modeled hurricane losses provided by AIR do not include LAE. Therefore, it is necessary to develop LAE provisions to be applied to these losses for use in pricing and hurricane exposure management. In order to account for the LAE associated with hurricane losses, we have applied a factor of 1.20 to the modeled losses for all property lines. The selection of this provision was based on a study of the LAE associated with hurricane losses for Allstate for ratemaking purposes.

Methodology:

Loss, allocated loss adjustment expense, and unallocated loss adjustment expense data for hurricane events from 2005 through 2017 were analyzed. These years were selected as the prevailing claims settlement practices better reflect the current practices. Additional adjustments to historical unallocated expenses were made where needed to best represent the expected claims staffing model and costs. Tropical storms are not included in the LAE analysis, as they are not simulated in the modeled loss data. A ratio of loss adjustment expenses to losses was developed.

V. ACTUARIAL STANDARDS OF PRACTICE

The rules and procedures as set forth in ASOP38-Catastrophe Modeling (for All Practice Areas) were applied in reviewing the modeled losses.

Allstate relies on AIR Worldwide, the developer of the model, as experts for those aspects of the model that are outside of the Allstate actuaries' area of expertise. AIR and Allstate's Catastrophe Modeling and Analytics Team (CMAT) have a strong working partnership that allows Allstate to work closely with AIR to better understand changes in the models, changes to Allstate's modeled loss estimates, and modeling concepts in general. Allstate's Catastrophe Modeling and Analytics Team's understanding of the model comes through multiple forums, such as technical documents prepared by AIR, on-site visits for training purposes, webinars, and client conferences.

Allstate's CMAT performs extensive analyses to evaluate if the changes in the modeled loss estimates are consistent with what would have been expected to occur. These expectations are based on Allstate's knowledge of what coverage mixes, amount of insurance changes, or deductible changes have taken place since the previous model run as well as what model updates or improvements have been made by AIR since the previous model.

Through these analyses, Allstate generates questions for AIR relating to (among many others): the generation of loss-causing events, frequency and severity changes, damage function changes,

and incorporation of new scientific data. Through a cooperative effort between AIR and Allstate, these questions are researched in order to confirm that the changes in modeled loss estimates are consistent with the enhancements made to the model as well as with any shifts in Allstate exposure.

Once the analysts on Allstate's CMAT are satisfied that the changes in modeled losses are explainable, the findings are presented to an expanded group of actuaries from both the Pricing Team and CMAT during an internal actuarial peer review process. This provides a forum for the senior actuarial group and those actuaries responsible for rate filings based on modeled loss estimates to become comfortable that due diligence was performed in accordance with ASOP 38 as well as for the actuarial group to approve both the modeled results and any modeled adjustments.

CONTINGENCY FACTOR SUPPORT
EXPLANATORY MEMORANDUM

This memo provides explanation regarding Castle Key's methodology for calculating a contingency provision to be used in its Condominium rate level.

Actuarial Standard of Practice (ASOP) No. 30, *Treatment of Profit and Contingency Provisions and the Cost of Capital in Property/Casualty Insurance Ratemaking*, defines the contingency provision for ratemaking purposes as follows: A provision for the expected differences, if any, between the estimated costs and the average actual costs, that cannot be eliminated by changes in other components of the ratemaking process. ASOP No. 30 goes on to state that:

- The actuary should include a contingency provision in the rates if assumptions used in ratemaking produce cost estimates that are not expected to equal average actual costs, and if the difference cannot be eliminated by changes in other components of the ratemaking process.

- While estimated costs are intended to equal average actual costs over time, differences between estimated and actual risk transfer costs may be expected in any given year. If a difference persists, the difference should be reflected in the ratemaking calculations as a contingency provision. The contingency provision is not intended to measure the variability of results and is not expected to contribute to profit.

Estimating the impact of costs that "cannot be eliminated by changes in other components of the ratemaking process" can be a challenge, and there has not yet emerged an ideal methodology for it.[1] Steven G. Lehmann, in his paper titled *Contingency Margins in Rate Calculations* notes, "How do you measure the 'unmeasurable'? Some may argue that measurement of the contingency factor is impossible because, by their very nature, contingencies are events which are not susceptible to treatment in the normal ratemaking approach – things you cannot plan for" (pg 227). As a result, historically, some actuaries have simply built in a provision that seemed "reasonable" using actuarial judgment. Conversely, Allstate has completed two different analyses intended to help give guidance as to what is a reasonable contingency provision. One approach is to determine what portion of historical losses came from events that were not intended to be covered. The other approach is to compare expected losses to actual losses over a long period of time to see if a difference persists. Each approach is described in detail below.

<u>Unexpected Loss Analysis (ULA)</u>
Even if an actuary has available relevant, credible data and uses the best, state-of-the-art actuarial techniques, there may still be instances where estimated future costs differ from actual future

[1] CAS literature has been surprisingly quiet on contingency provision methodology. The most recent paper addressing the issue was written in 1985 by Steven G Lehmann.

costs. The factors causing this situation to occur are outside the actuary's ability to predict and the insurer's ability to control. Examples would include (but not be limited to) court decisions, legislative action, and media influence on the public's behavior.

In spite of the inability to foresee specific events, an insurer may look back at recent history and identify past events that triggered unexpected payments. Given the highly regulated nature of the property and casualty insurance industry and the large amounts of money that flow through an insurance organization, it is reasonable to assume that adverse court decisions and similar unexpected events will occur again in the future. Courts and regulatory bodies are likely to continue to respond to lawsuits and other attempts at unexpected application of an insurance policy's coverage. As outlined in the Actuarial Standard of Practice referenced above, these events should be accounted for in ratemaking in the form of a contingency provision.

The unexpected loss methodology for calculating a contingency provision allows for more specificity around the type of events that are included. We have reviewed loss experience and have identified a number of representative events that are appropriate to a contingency provision, due to their unanticipated nature. Considered events include the following: court decisions redefining the cause of loss for earth movement- and landslide-related loss, sinkholes, failure to disclose (in connection with sale of a home), oil tank leakage, foundation slab losses, mold, methamphetamine lab damage, legislated exceptions to policy language, flooding, lead paint poisoning, imminent collapse, terrorism, radiant floor heating systems, dog bites, and drug cartel wars. Identifying these events through Allstate claim file narratives allows us to exclude claims that are not appropriate to a contingency provision, such as normal low frequency, high severity events and regulatory delay situations. The effect of inflation is also excluded.

Some of these losses are too old to obtain reliable loss data at the claim level of detail. Some of these losses are too new to have worked into our data yet. Some events are excluded because, even with sophisticated computer programs, losses are not specifically tracked and so can't be separated from other loss data for inclusion in Allstate's computations. Some events simply did not produce a frequency of loss to materially impact our calculations. However, each event mentioned above illustrates that unforeseen loss does occur. This can be the case when a legislative or court decision expands the scope of Allstate's policy coverage, or when the media unexpectedly focuses attention on a health issue or other item of public concern. Other as-yet-unknown influences that Allstate cannot predict or price for will also likely affect claims payments in the future.

In order to estimate an appropriate contingency provision, we have selected a group of events from the above list of considered events (including oil tanks, slab losses, mold and flooding) for which we can obtain more detailed loss data. It is not our intention to price these specifically named events, but to use these events as a proxy for unforeseen events occurring in the future. Issues which triggered payments over several years cannot be considered "unexpected" for an indefinite period of time. In these cases, we have judgmentally included losses from the first three years following the initial event. After three years we assume that these losses are present in our indications data and that we have priced sufficiently for the event's exposure in our rates. Some events are of shorter duration and so fewer than three years of losses are included in the calculations. Note also that data includes some low frequency, high severity losses. Such losses

are more appropriately accounted for with a long-term provision rather than in a contingency provision, and Allstate does calculate an adequate weather provision (theoretically sound and calculated over a sufficiently long period of time). However, the legislative, media and other influences that generate unexpected losses can also affect such losses. Therefore, these losses are included in our analysis when they stem from one of the issues in question. Losses are included for Allstate's Owners, Renters and Condo forms.

Attachment D, Exhibit 8 shows the sum of all claims divided by countrywide homeowners accident year non-catastrophe losses from 1996 – 2003, adjusted for expense provisions. This time period was chosen to match the time period of losses readily available to us (our claim files older than 1996 cannot be effectively reviewed to extract specific losses). Our analysis was completed in 2004, and due to systems modifications since then, retrieving data at this level of detail would require extensive effort. Losses for some events have been adjusted downward to reflect the fact that, despite the sophistication of our analysis, some claims unrelated to the issue in question can be unintentionally included in the loss totals.

Expected Loss Versus Actual Loss Analysis (ELVALA)

As noted above, ASOP 30 states: "While estimated costs are intended to equal average actual costs over time, differences between estimated and actual risk transfer costs may be expected in any given year. If a difference persists, the difference should be reflected in the ratemaking calculations as a contingency provision." Thus, the goal of Allstate's second analysis is to determine if there is a persistent difference between actual and expected losses.

In this approach, a reasonable approximation of Allstate's rate-level indication methodology is applied to historical non-catastrophe losses, and an estimate of a future year's losses is calculated and compared to the actual losses for that year. For example, data from 1997, 1998, and 1999 is used to calculate an estimate of losses for the year 2000. This estimate is then compared to the actual losses for the year 2000. This process was repeated using data going back to 1995. However, note that we have opted to allow the actual losses to develop for three additional years in order to have an actual loss value that is close to its ultimate value. As a result, the most recent data used in the analysis will always lag behind the current year by approximately three years.

In addition, we have removed from the data for this analysis the large, unexpected losses that were discussed above in the ULA section. Thus, what remains here is a "persistent" difference between the average expected and actual losses. Given that this analysis removes the effect of the large, unexpected losses, the ULA and ELVALA could be considered to be estimating separate and distinct causes of persistent bias. As such, it would be reasonable to conclude that the calculated percentage differences in the two analyses could be considered cumulatively in defense of the selected contingency provision.

Attachment D, Exhibit 8 shows the results of the historical comparison of expected and actual losses. This long-term difference is then divided by total losses to get a percentage, and is then adjusted for expense provisions.

Revision History

Revision Date	Description
July 20, 2021	Initial publication

1. ***Identify the particular Catastrophe Model that is used in this filing to:***
   a. ***project hurricane losses***
   b. ***determine probable maximum loss levels***
   c. ***determine the cost of reinsurance***

   This identification should include the name and location of the firm that created the model, the name of the model, and the version number of the model.

For hurricane losses used in the modeled hurricane provision, the catastrophe model used is the AIR Hurricane Model for the U.S., Version 1.0.0[1]. The model was created by AIR Worldwide, 2 Avenue de Lafayette, 2nd Floor, Boston, MA, 02111.

2. ***In an electronic format, provide the detailed input that you provided to the modeler along with a list of all adjustments made by you prior to giving the input to the modeler necessary to conform this input to the model's input requirements. Be sure to provide a detailed description of each data field. Include any default values that you specified for missing or invalid information. Describe any exposures affected by this filing that were not included in your input to the model. Describe any exposures included in your input to the model that are not part of this rate filing. Note – if the model was run in-house, you should still provide the detailed input along with a statement of who was responsible for running the model and what controls were in place to ensure that the version of the model provided to you was not altered.***

Please see Attachment K (Exposure Specification Document) for the detailed input and the description of each data filed. Castle Key modeled their exposures using 6/30/2022 exposure data for the modeled hurricane provision. Exposures from the planned non-renewal policies have been removed.

3. ***In an electronic format, provide the ACTUAL complete model output, documentation, and reports provided to you by the modeler (or produced by you if you ran this model in-house).***

Please see Attachment L (Output Specifications Document) for the detailed output and for the description of each data field.

Castle Key has also included a link to the AIR Technical Document relating to the AIR Hurricane Model for the U.S v1.0.0 as submitted to the Florida Commission.
https://www.sbafla.com/methodology/Portals/Methodology/ModelSubmissions/2021/AIR_2019_FCHLPM_Submission_20210519.pdf?ver=2021-06-17-103335-633

Form A-1 as submitted to the Florida Commission provides modeled loss costs by construction type and coverage for each ZIP Code in the FHCF sample data set. Please see Attachment C.

[1] AIR has submitted the AIR Hurricane Model for the U.S. Version 1.0.0 and this version has been found acceptable by the FCHLPM.

©2021 AIR Worldwide

4. ***Provide an explanation with appropriate supporting information showing how the results from the model were included in column (30) of the Rate Indication Forms. No modifications or adjustments may be made to the results of the model.***

No modifications or adjustments have been made to the results of the model. A detailed explanation showing how results from the model were included in column (30) of the Rate Indication Forms has been included in the Standardized Rate Indications Workbook Memorandum.

5. ***Provide a listing of experts that you relied on concerning those aspects of the model outside your area of expertise.***

AIR's staff is comprised of a multi-disciplinary team of experts. A list of the employees that have worked on the U.S. Hurricane Model, and their credentials, is provided in Standard G-2, Disclosure 2A of AIR's model submission to the Florida Commission on Hurricane Loss Projection Methodology (FCHLPM or the Commission). This information is also provided as Attachment B.

6. ***State the extent to which the model has been reviewed or opined on by experts in the applicable fields, including any known significant differences of opinion among experts concerning aspects of the model that could be material to your use of the model.***

AIR scientists are in ongoing contact with peers in the industry and academia to stay up to date on the current state of the art in hurricane modeling and wind damageability. The model has been reviewed by the FCHLPM and the Professional Team as well as other external experts. The AIR model also has been peer reviewed by a list of external experts, which is provided in response to question 30.

There are differences of opinion within the scientific community regarding the link between elevated sea surface temperatures (SSTs) and hurricane landfall activity, and the use of climate conditioned hurricane catalogs. AIR's Warm Sea Surface Temperature (WSST) Conditioned catalog is released to clients as a supplement to, rather than a replacement for, AIR's standard view of risk, which is based on more than 100 years of historical data and has performed very well over the past 20 years—including during the 2004 and 2005 hurricane seasons that produced a large number of U.S. hurricanes.

7. ***Provide the basic components of the model and your understanding of how such components interrelate within the model.***

Figure 1 illustrates the component parts of the AIR Hurricane Model for the U.S. (dashed boxes). Each component represents both the ongoing efforts of the research scientists and engineers responsible for its design and the computer processes that occur as the simulations are run.

©2021 AIR Worldwide

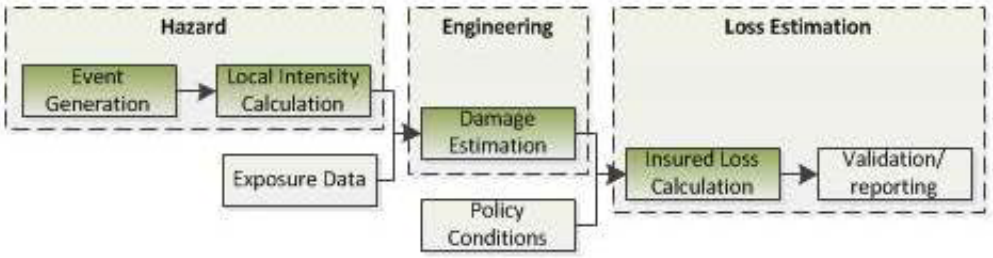

Figure 1. AIR Hurricane Model for the U.S. Components

Methodology

The AIR Research team collects the available scientific data pertaining to the meteorological variables critical to the characterization of hurricanes and therefore to the simulation process. These primary model variables include landfall location, central pressure, radius of maximum winds, forward speed and storm heading. Data sources used in the development of the AIR Hurricane Model for the U.S. include the most complete databases available from various agencies of the National Weather Service, including the National Hurricane Center. All data is cross-verified. If data from different sources conflict, a detailed analysis and the use of expert judgment are applied to prepare the data for modeling purposes.

Event Generation Component

This first module of the AIR tropical cyclone model is used to create the stochastic storm catalog. More than one hundred years of historical data on the frequency of hurricanes and their meteorological characteristics were used to fit statistical distributions for each parameter. By stochastically drawing from these distributions, the fundamental characteristics of each simulated storm are generated. The result is a large, representative catalog of potential events.

Landfall Location: There are 62 potential landfall segments in the AIR Hurricane Model for the U.S., each representing approximately 50 nautical miles of smoothed coastline from Texas to Maine. There is an additional segment for the Florida Keys. To estimate the probability of a hurricane occurring on each of these segments, a cumulative distribution of landfall locations is developed as described below. Once a segment is chosen, the landfall location is picked uniformly along the segment. The coastline is first smoothed for irregularities such as inlets and bays. The actual number of hurricane occurrences is then tabulated for smoothed 50-nautical-mile segments. The actual number of occurrences for each segment is then smoothed by setting it equal to the weighted average of a set of successive data points centered on that segment. This smoothing technique was selected because it has been used in other climatological studies and because it maintains areas of high and low frequency and also accounts for the lack of historical landfalls in certain portions of the coastline.

Bypassing Storms: The AIR Hurricane Model for the U.S. generates bypassing as well as landfalling storms through a track generation procedure that follows each simulated hurricane from the time of its inception until it dissipates. A bypassing hurricane is one that does not make landfall in Florida as a hurricane but does cause damaging winds over land.

©2021 AIR Worldwide

Meteorological Characteristics: The simulated frequency of hurricanes is consistent with the frequency observed historically over the period 1900–2018. Probability distributions are estimated for central pressure and forward speed for 31 one-hundred-nautical-mile segments of coastline. Separate distributions are estimated for each of these segments because the likely range and probabilities of values within each range for these variables depend upon geographic location and, in particular, latitude. For example, intense hurricanes are more likely to occur in southern latitudes where the water is warmer. Storms affecting the coast in northern latitudes tend to be larger and faster moving on average. Radius of maximum winds is represented using a regression model that relates the mean radius to central pressure and latitude.

Storm Heading at Landfall: Landfall angle is measured clockwise (+) or counterclockwise (-) with 0 representing due North. Separate distributions for storm heading at landfall are estimated for each 50- nautical-mile segment of coastline. Storm heading is modeled as combined Normal distributions, and bounded based on the historical record, geographical constraints, and meteorological expertise. Diagnostic tests performed show a reasonable agreement between historical and modeled values.

Storm Track: The methodology used to generate storm tracks is based on the information available in the National Hurricane Center HURDAT2 database for the period 1900–2007. This database provides track information for more than 1,000 North Atlantic storms at six-hour time intervals. Time series techniques have been used to determine the dependence structure present in key model variables from one time period to the next. Time series models that describe the dependence in the historical data are used in the generation of simulated tracks. For example, a first-order Markov model with transition probabilities estimated from the historical data is used to generate changes in track direction of simulated storms. The storm tracks generated using this approach are realistic and resemble storm tracks that have been observed for historical storms.

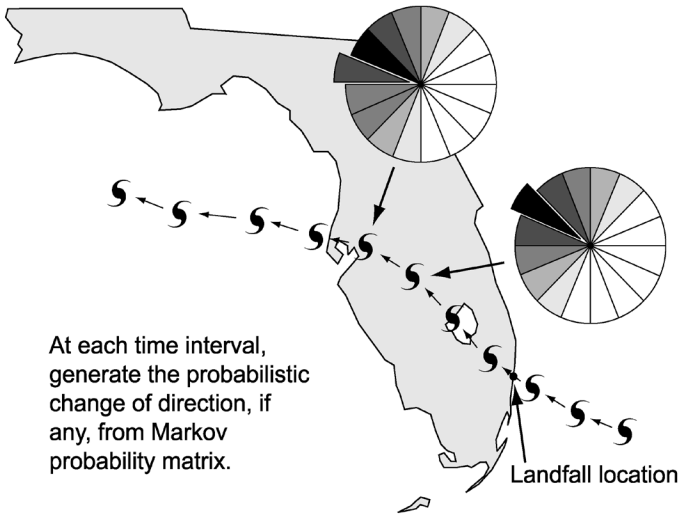

Figure 2. Storm Track Generation

AIR uses the event generation component of the model to simulate 50,000 years of potential hurricane activity.

©2021 AIR Worldwide

Wind Field Generation Component

The model simulates each storm's movement along its track. A complete time profile of wind speeds is developed for each location affected by the storm, thus capturing the effect of duration of wind on structures as well as peak wind speed. Calculations of local intensity take into account the effects of the asymmetric nature of the hurricane wind field, storm filling over land and radial variation of wind speeds from the radius of maximum winds. The model also uses surface roughness information to account for boundary layer modification of the winds by the local land surface.

Gradient Wind Reduction Factor (GWRF): The model uses a stochastic GWRF, which varies from storm to storm. The mean value, the distribution about the mean and the radial profile of the GWRF have been developed based on analyses of dropsonde (GPS dropsonde data are provided courtesy of the NOAA/AOML/Hurricane Research Division in Miami, Florida), as well as results from published literature (Franklin et al., 2003, Powell et al., 2009). The GWRF is adjusted based on the Peak Weighting Factor (see below) and the distance from the eye. Both parameters (GWRF and PWF) are generated jointly using a bounded Bivariate Normal Distribution (based on Casella and Berger, 1990).

Peak Weighting Factor (PWF): The PWF is a stochastic parameter used to reflect the vertical slant in the hurricane eye (Powell et al., 2009). As mentioned above, the PWF and GWRF are generated jointly using a bounded Bivariate Normal Distribution.

Damage Calculation Component

AIR scientists and engineers have developed damage functions that describe the interaction between buildings, both their structural/nonstructural components and their contents, and the local intensity to which they are exposed. These functions relate the mean damage level as well as the variability of damage to the measure of intensity at each location.

The damage functions vary according to construction class and occupancy because different structural types will experience different degrees of damage. For example, a home of masonry construction generally performs better in a hurricane than does a home of wood frame construction, all things being equal. The AIR Hurricane Model for the U.S. estimates a complete distribution around the mean level of damage for each local intensity and each structural type. Losses are calculated by applying the appropriate damage function to the replacement value of the insured property.

The AIR damageability relationships incorporate the results of well-documented engineering studies, damage surveys and analyses of available loss data. AIR engineers have surveyed all significant loss causing events since Hugo in 1989 as part of the ongoing process of refinement and validation of these functions. In addition, actual claims data from recent hurricanes, supplied to AIR by client companies, have been extensively analyzed.

©2021 AIR Worldwide

Insured Loss Calculation Component

Insured losses are calculated by applying the policy conditions to the total damage estimates. Policy conditions may include deductibles by coverage, site-specific or blanket deductibles, coverage limits and sublimits, loss triggers, coinsurance, attachment points and limits for single or multiple location policies, and risk-specific reinsurance terms.

The interactions among major model components are illustrated in Figure 3.

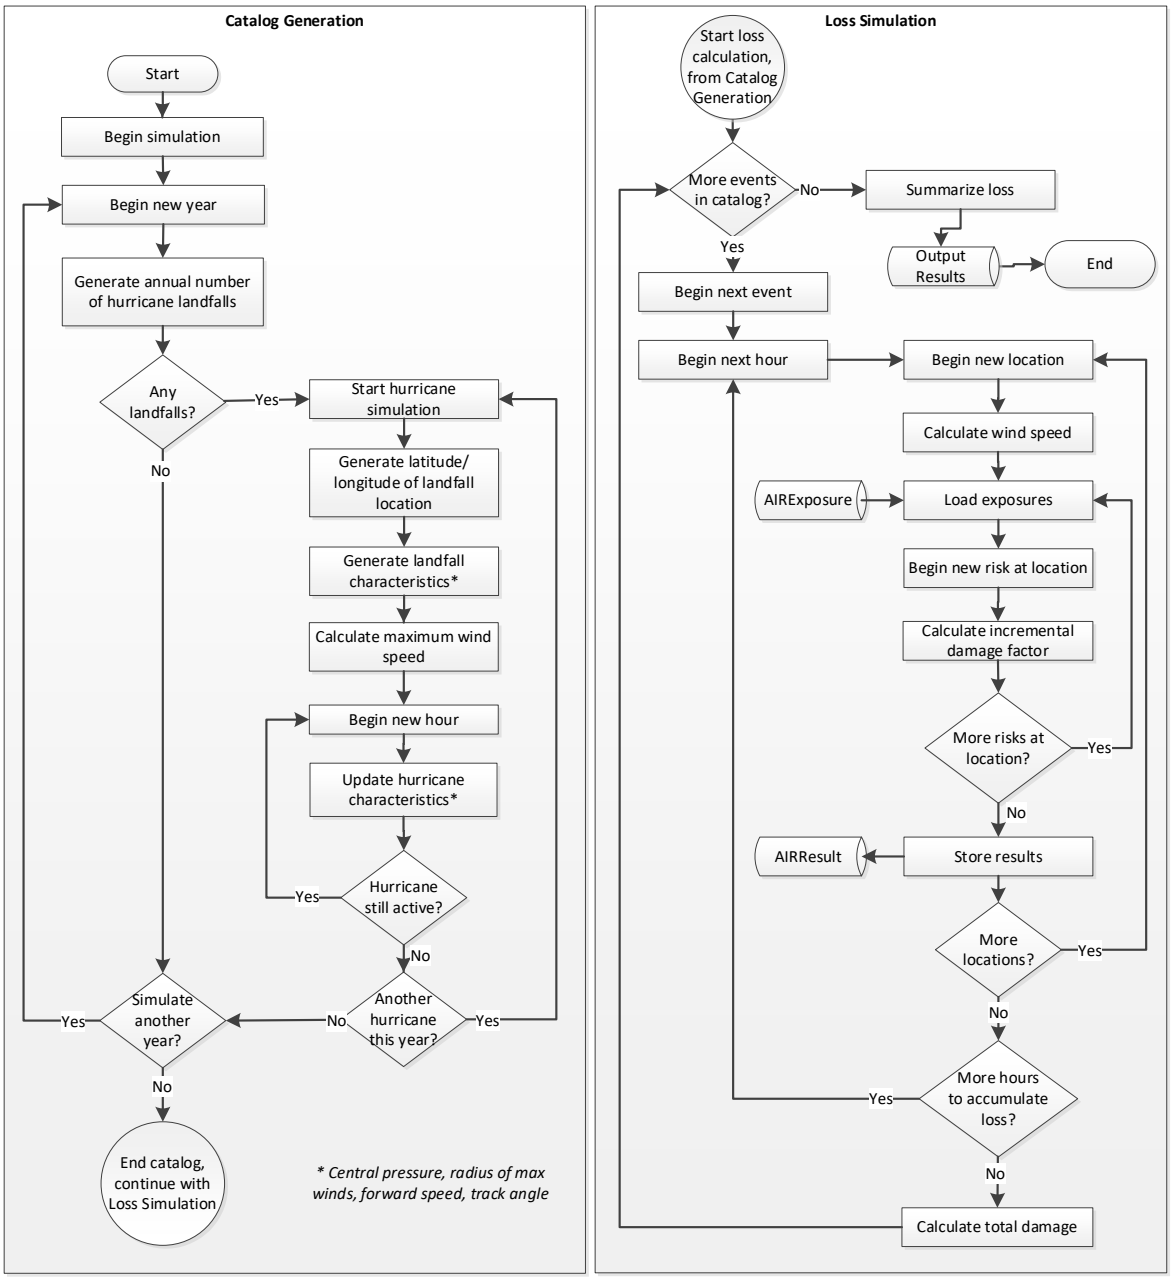

Figure 3. Flowchart of the model component interactions in the AIR Hurricane Model for the U.S.

©2021 AIR Worldwide

8. ***Explain how the model was tested or validated and the level of independent expert review and testing.***

AIR scientists and engineers validate the models at every stage of development by comparing model results with actual data from historical events. The simulated event characteristics parallel patterns observed in the historical record and resulting loss estimates correspond closely to actual claims data provided by clients. Internal peer review is a standard operating procedure and is conducted by the AIR professional staff of over 100 scientists and engineers.

AIR models have also undergone external review by independent experts as well as an extensive review conducted by the FCHLPM. Please see question 30 for more details of the external peer reviews.

In recent years, the industry has witnessed a transfer of catastrophe risk to the capital markets through the issuance of catastrophe, or "cat," bonds. AIR models have been used in many of the transactions that have been based on catastrophe modeling. Investors have relied on the research and due diligence performed by the securities rating agencies—Standard & Poor's, Moody's Investors Service, and Fitch Investors Service—to make their investment decisions. As part of the due diligence process, the AIR models and their underlying assumptions undergo extensive scrutiny by outside experts hired by these rating agencies as well as by their own experts. Detailed sensitivity analyses of the major components of the model are performed. Stress testing each component for stability and robustness.

9. ***Explain how you determined that the particular model you used was appropriate for use in this filing.***

The response to question 10 below demonstrates the many due diligence efforts Castle Key takes before using the results from the model. After validation is complete for both exposures and modeled losses, an internal peer review is held with a cross-functional team which includes many credentialed actuaries. This team determines whether it is appropriate to use results from the model, subject to any necessary adjustments, such as LAE.

10. ***Explain how you examined the model output for reasonableness, considering factors such as the following:***
    - ***a. The results derived from alternate models or methods.***
    - ***b. How historical observations compare to the results produced by the model.***
    - ***c. The consistency and reasonableness of relationships among various output results.***
    - ***d. The sensitivity of the model output to variations in your input and model assumptions.***

©2021 AIR Worldwide

a) Castle Key has purchased extensive countrywide modeling services from AIR Worldwide Corporation (then Applied Insurance Research, Inc.) since 1995. AIR was selected from a field of four of the premiere-modeling firms of the time. During that same year, Castle Key also contracted with Risk Management Solutions, Inc. (then Risk Management Software, Inc.) and with CoreLogic (then EQECAT, Inc.), for Florida hurricanes. Castle Key concluded that the statewide estimates from all three models were fairly consistent at that time. For the calendar periods of 1996-1998 both AIR and RMS contracts were maintained, and Castle Key worked closely with both companies to understand their models and the results of running them against Castle Key exposures. The RMS contract was terminated at the end of 1998 as a result of prudent internal expense management. From 1999 – 2002 Castle Key contracted with AIR exclusively. Castle Key again contracted with RMS and AIR to run hurricane models from 2002 – 2005. Starting in 2006, Castle Key has maintained an annual contract with AIR and has periodically contracted with RMS for specific Work Orders. Through these relationships, Castle Key continues to feel confident that the AIR model is appropriate for ratemaking in all states where hurricane modeling is used.

b) AIR has performed an extensive study on modeled vs. actual historical losses for the FCHLPM. The tables that show the comparisons done for the study is included in Standard S-5, Disclosure 1 of AIR's model submission (https://www.sbafla.com/methodology/Portals/Methodology/ModelSubmissions/2021/AIR_2019_FCHLPM_Submission_20210519.pdf?ver=2021-06-17-103335-633) as well as in the response to question 27 in this document.

c) The analysts on Castle Key's Catastrophe Modeling and Analytics Team do extensive checks of the output data to ensure there is no discontinuity. Comparisons are made of modeled loss differences due to model changes for a notional exposure set, and actual modeled loss shifts due to model changes based on an actual exposure set. Annual and event frequency and severity differences are compared using the same process. These analyses are performed to evaluate if the changes in the modeled loss estimates are consistent with what would have been expected to occur. These expectations are based on Castle Key's knowledge of what coverage mixes, amount of insurance changes, or deductible changes are present in the exposures used, as well as what model updates or improvements have been made by AIR since the previous model.

   Through this analysis, Castle Key generates questions for AIR relating to (among many others): the generation of loss-causing events, frequency and severity changes, damage function changes, and incorporation of new scientific data. Through a cooperative effort between AIR and Castle Key, these questions are researched in order to confirm that the changes in modeled loss estimates are consistent with the enhancements made to the model.

   Once the analysts on Castle Key's Catastrophe Modeling and Analytics Team are satisfied that the changes in modeled losses are explainable, the findings are presented to an expanded group of actuaries from both the Pricing and Catastrophe Modeling and Analytics Teams during an internal peer review process. This provides a forum for the senior actuarial group and those actuaries responsible for rate filings based on modeled loss estimates to become comfortable that due diligence was performed in accordance with ASOP 38 as well as for the actuarial group to gain support in utilizing both the modeled results and any modeled adjustments.

©2021 AIR Worldwide

d) In the analysis performed for the FCHLPM submissions, variations in loss costs result in model sensitivity to different policy forms, construction types, and geographic regions of the state. AIR also conducted tests to ensure reasonableness of different model assumptions. Tests are completed for different variables included but not limited to the following: central pressure, radius of maximum wind, forward speed, far field pressure, the gradient wind reduction factor, and the peak weighting factor.

11. ***Provide all available comparison of model results with actual historical observations for your company or group. These comparisons should be provided by policy type and territory within policy type.***

Table A: Actual vs. Modeled Losses for Selected Historical Storms

Event	Actual Loss ($)	Modeled Loss ($)
Irma	142,774,054	83,009,629
Michael	192,624,741	121,559,990
Total	**335,398,796**	**204,569,618**

Table B: Actual vs. Modeled Losses By Policy Type

Policy Type	Event	Actual Loss ($)	Modeled Loss ($)
Homeowners	Irma	138,940,062	76,432,188
Homeowners	Michael	188,326,035	118,166,272
Total Homeowners	**Total**	**327,266,097**	**194,598,461**
Renters	Irma	1,947,837	4,921,531
Renters	Michael	3,866,378	3,067,928
Total Renters	**Total**	**5,814,216**	**7,989,459**
Condos	Irma	1,886,155	1,655,909
Condos	Michael	432,328	325,790
Total Condos	**Total**	**2,318,483**	**1,981,699**

12. ***State and provide complete support for the credibility that you have assigned to the output of the model by policy type and territory within policy type.***

At this time, Castle Key feels that the AIR model provides the best estimate of their expected annual hurricane losses. A credibility weighting of 100% has been applied to the AIR model for all policy types and territories since Castle Key has not used any other source to estimate their expected annual hurricane losses.

13. ***Provide the hurricane data set used to develop the model. Include the source of this information. For any hurricanes not included in the Official Hurricane Set of the Florida Commission on Hurricane Loss Projection Methodology, provide an overall estimate of their impact on the loss cost projections. Also, explain why they are included and provide complete supporting data/information. Finally, state whether or not the Official Hurricane Set has been similarly altered in past versions of the model.***

©2021 AIR Worldwide

The hurricane data set used to develop the AIR model is the HURDAT2 database released by the National Hurricane Center (NHC) with a vintage of July 1, 2019 and covers the historical events span from year 1900-2018. This database also incorporates reanalysis for storms up to and including 1960. Additionally, when landfall information was not available in HURDAT2, AIR supplemented the database with landfall information available in Appendix A in NOAA Technical Memorandum NWS NHC-6, Tropical Cyclone Reports from NHC (available at http://www.nhc.noaa.gov/pastall.shtml), peer-reviewed publications, UNISYS, Extended Best Track Dataset, and NOAA Technical Reports NWS-23 and NWS-38 to generate storm characteristics at landfall.

The modeled loss estimates for all the historical events included in the Official Hurricane Set (or also known as the Base Hurricane Storm Set) are available in Form A-2 (FHCF 2017 Data) of AIR's model submission to the FCHLPM. The Professional Team also reviewed and found the modeled loss estimates reasonable during their on-site audit.

14. ***Identify the hurricane characteristics (e.g., central pressure or radius of maximum winds) that are used in the model. For hurricane characteristics modeled as random variables, provide the probability distributions used along with complete supporting data/information for the derivation and reasonableness of each distribution.***

Hurricane characteristics used in the AIR model are summarized in Table 1, and described in more detail in the sections that follow.

Table 1. Summary of Hurricane Characteristics

Characteristic	Random Variable?	Distribution Type/ Methodology
Intensity	Yes	Weibull
Radius of Maximum Winds	Yes	Normal
Storm Track	Yes	Markov Chain Methodology
Forward Speed	Yes	Lognormal
Storm Heading	Yes	Normal
Gradient Wind Reduction Factor	Yes	Bivariate Normal
Peak Weighting Factor	Yes	Bivariate Normal

Intensity: The model utilizes central pressure as the primary hurricane intensity variable. The historical data are modeled using Weibull distributions where the parameters are estimated for each of the thirty-one 100-nautical-mile coastal segments as well as for larger coastal regions, with the final distribution being a mixture of the two. The Weibull form was selected based on goodness-of-fit tests with actual historical data.

Radius of Maximum Winds: The probability distribution for radius of maximum winds (Rmax) is modeled using a regression model of the form:

$$R_{max} = f(Cp, \text{latitude}) + \varepsilon,$$

©2021 AIR Worldwide

where f(Cp, latitude) represents the mean of Rmax for given values of central pressure and latitude. The error term, ε, is assumed to be normally distributed. The parameters in this regression model are estimated using data available in NOAA Technical Report NWS-38, the HURDAT2 Reanalysis Project, and the DeMaria Extended Best Track Dataset (EBTRK). The final distribution is truncated using limits that depend on central pressure and are consistent with the range of historically observed values. Rmax also varies after landfall, following an autoregressive model.

Landfall Location: There are 62 potential landfall segments in the model, each representing ~50 nautical miles of smoothed coastline from Texas to Maine. In Florida, there are 17 landfall segments. The southernmost Florida segment includes a consideration for the Florida Keys. Historical hurricane occurrences since 1900 are used to estimate a smoothed locational frequency distribution. The smoothing technique maintains areas of high versus low frequency and also accounts for the lack of historical landfalls in certain portions of the coastline. Once a segment is chosen, the landfall location is assigned randomly along the segment, from a uniform distribution.

Forward Speed: Forward speed is modeled using a lognormal distribution with parameters estimated for each 100-nautical-mile coastal segment. Separate distributions are estimated for each of these segments to capture the dependence of this variable upon geographical location, particularly latitude. Forward speed is allowed to vary after landfall, following an autoregressive model. The bounds on forward speed are latitude dependent.

Storm Heading: The probability distributions for storm heading at landfall are defined on the 50-mile coastal segments. Upper and lower bounds are placed, based on geographical constraints. The distributions used are mixtures of Normal distributions bounded based on geography and the historical record.

Gradient Wind Reduction Factor (GWRF): The model uses a stochastic GWRF, which varies from storm to storm. The mean value, the distribution about the mean and the radial profile of the GWRF have been developed based on analyses of dropsonde data from 2002 to 2005 (GPS dropsonde data are provided courtesy of the NOAA/AOML/Hurricane Research Division in Miami, Florida), as well as results from published literature (Franklin et al. 2003, Powell et al. 2009). For a given storm, the GWRF is adjusted based on the Peak Weighting Factor (see below) and the distance from the eye. Both parameters (GWRF and PWF) are generated jointly using a bounded Bivariate Normal Distribution (based on Casella and Berger, 1990).

Peak Weighting Factor: The PWF is a stochastic parameter used to reflect the vertical slant in the hurricane eye (Powell et al., 2009). As mentioned above, the PWF and GWRF are generated jointly using a bounded Bivariate Normal Distribution.

The following hurricane parameters are modeled as functions:

Peripheral Pressure: The model uses a latitude dependent peripheral pressure, parameterized based on the work of Knaff and Zehr (2007) as well as analyses of historical storms.

Radial Adjustment to the Gradient Wind Reduction Factor: The stochastically drawn GWRF also varies with distance from the eye and PWF, following a Radial Adjustment Function (RAF).

The following reference materials have been reviewed by AIR researchers and used in the development and refinement of the hazard module of the U.S. Hurricane Model.

©2021 AIR Worldwide

A comprehensive list of the meteorological references is provided in Standard G-1, Disclosure 4 of AIR's model submission to the FCHLPM (available at https://www.sbafla.com/methodology/Portals/Methodology/ModelSubmissions/2021/AIR_2019_FCHLPM_Submission_20210519.pdf?ver=2021-06-17-103335-633.

15. ***Provide all the vulnerability functions used in the model along with complete supporting data/information for the derivation and reasonableness of each function.***

The AIR building vulnerability functions are categorized by construction, occupancy, and height. Secondary risk characteristics are implemented as a modification to the underlying vulnerability functions and described in Attachment D and can be implemented through both direct user input and/or through input of exposure location and year of construction information.

The AIR model has many unique vulnerability functions depending on the building construction type, height, occupancy type, year-built, gross area as well as secondary features. Generalizations of these construction types, which are representative of our vulnerability classifications, are given in Table 2. The AIR Hurricane Model for the U.S. includes year-built categories: pre-1995, 1995-2001, 2002-2011 and post-2011. Between 1995 and 2015 there is a year-by-year change in the year-built adjustment to account for structural aging, a general behavior in the vulnerability observed in actual loss data.

Table 2. Residential Construction Types in the AIR Model

Residential and Apartment or Condominium Buildings	
Construction Type	**General Description**
Wood Frame	Wood frame structures tend to be mostly low rise (one to three stories, occasionally four stories). Stud walls are typically constructed of 2 inch by 4 or 6 inch wood members vertically set 16 or 24 inches apart. These walls are braced by plywood or by diagonals made of wood or steel. Many detached single and low-rise multiple family residences in the United States are of stud wall wood frame construction.
Masonry Veneer	Wood frame structures with one width of non-load bearing concrete, stone or clay brick attached to the stud wall.
Unreinforced Masonry	Unreinforced masonry buildings consist of structures in which there is no steel reinforcing within a load bearing masonry wall, floors, roofs, and internal partitions in these bearing wall buildings are usually of wood.
Reinforced Masonry	Reinforced masonry construction consists of load bearing walls of reinforced brick or concrete-block masonry. Floor and roof joists constructed with wood framing are common.
Reinforced Concrete	Reinforced concrete buildings consist of reinforced concrete columns and beams.
Steel	Steel frame buildings consist of steel columns and beams.
Light Metal	Light Metal buildings are made of light gauge steel frame and are usually clad with lightweight metal or asbestos siding and roof, often corrugated. They typically are low-rise structures.
Unknown	Represents a weighted average of all of the above construction types except the manufactured homes

©2021 AIR Worldwide

Manufactured Homes	
Construction Type	**General Description**
Manufactured home with no tie-downs	This code would be used for manufactured homes with no anchoring systems present.
Manufactured home with partial tie-downs	This code would be used for manufactured homes when the tie downs are either over-the-top ties, or frame ties but not both or with fewer ties than recommended by the manufacturer.
Manufactured home with full tie-downs	This code would be used for manufactured homes when the anchoring systems are both over-the-top ties, and frame ties. Typically 10 frame ties and 7 over the top ties are required for full tie down in singlewide mobile homes.
Manufactured Homes	Represents a weighted average of tie-down types, including no tie-downs. This code would be used for manufactured homes (mobile homes) when the tie down information is unknown.

The AIR vulnerability functions have been developed by experts in both wind and structural engineering and based on published engineering research. The functions have been validated based on results of damage surveys and on actual claims data provided by client companies. The methods have been peer reviewed internally and by external experts and are theoretically sound. The vulnerability functions include probability distributions around the mean damage ratios to capture the uncertainty in damage at a given level of wind speed. These probability distributions have been developed based on actual insurance loss data and findings from damage surveys.

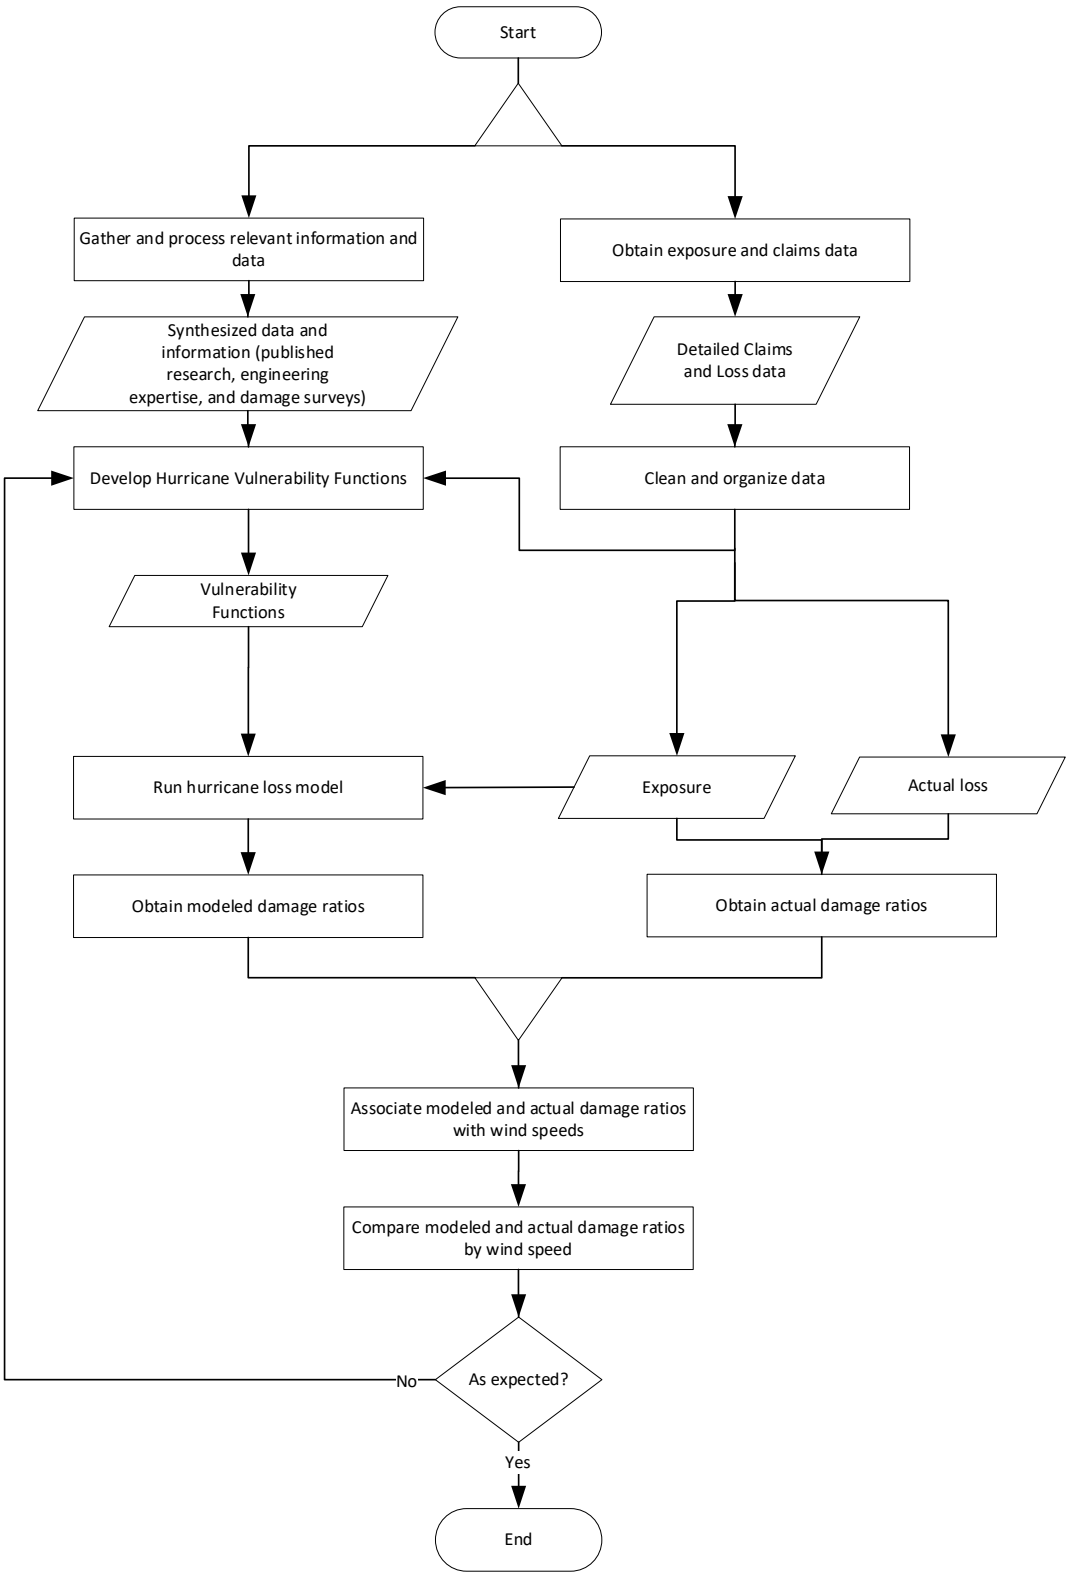

Figure 4. Derivation and Implementation of AIR Vulnerability Functions

©2021 AIR Worldwide

16. ***Provide any other distributions, functions, formulas, assumptions, factors, etc. used in the model. Include complete supporting data/information for the derivation and reasonableness of each distribution, function, formula, assumption, factor, etc.***

No other distributions, functions, formulas, assumptions, or factors are used in the model.

17. ***Show how all the distributions, functions, formulas, assumptions, factors, etc. interact to produce the final loss cost projections of the model.***

See response to question 7.

18. ***Demonstrate that loss cost relationships by type of coverage (structures, appurtenant structures, contents, additional living expenses) are consistent with actual insurance data. Include and identify the actual insurance data.***

AIR has compiled an extensive database of over 20 years of claims data for historical U.S. hurricanes from several major client companies. Experts at AIR have collected and analyzed over USD 15 billion of detailed loss data over the past two decades in order to validate modeled losses. More recently, AIR researchers have collected and analyzed commercial and residential claims data to the tune of USD 2.5 billion and 3.8 billion, respectively, from recent hurricanes such as Sandy, Isaac, Irene and Ike, in an effort to validate the modeled losses for these events. Further validation is undertaken after each damage survey, which AIR has conducted for every U.S. landfalling hurricane since Hurricane Hugo in 1989.

Figure 5 through Figure 7 compares modeled gross losses with actual gross losses obtained from different insurance client companies (indicated by letters) for residential buildings, contents, and time element, respectively. For all these figures, the modeled losses are based on exposure data provided by the client company at the time of the event. For those charts that compare modeled and actual losses, the loss values on the vertical axis are not displayed for client confidentiality purposes. The agreement between modeled and actual losses is good for all companies and hurricane events combined in comparison to individual company event combinations where some variability is seen and expected.

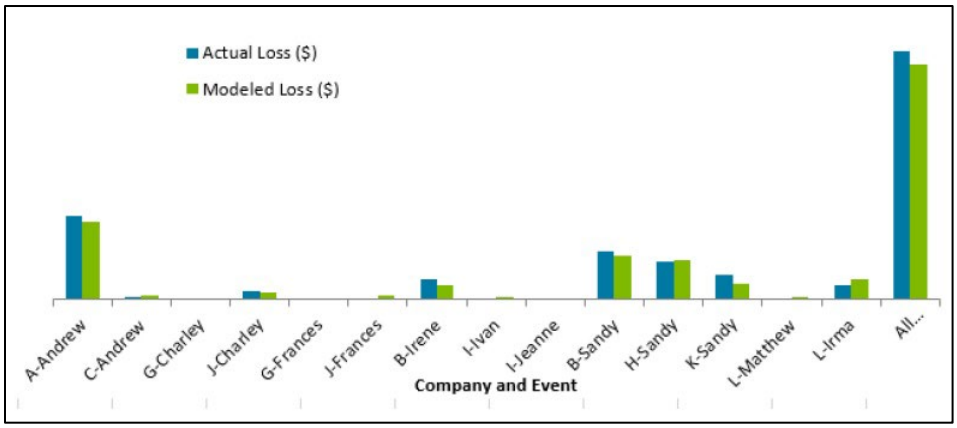

Figure 5. Actual and modeled gross loss from several different companies for residential building coverage

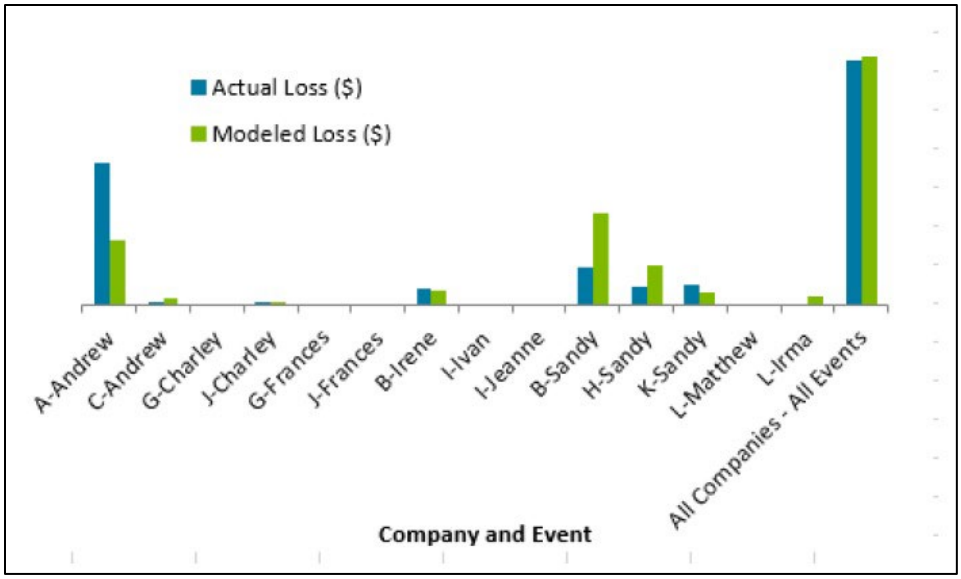

Figure 6. Actual and modeled gross loss from several different companies for residential contents coverage

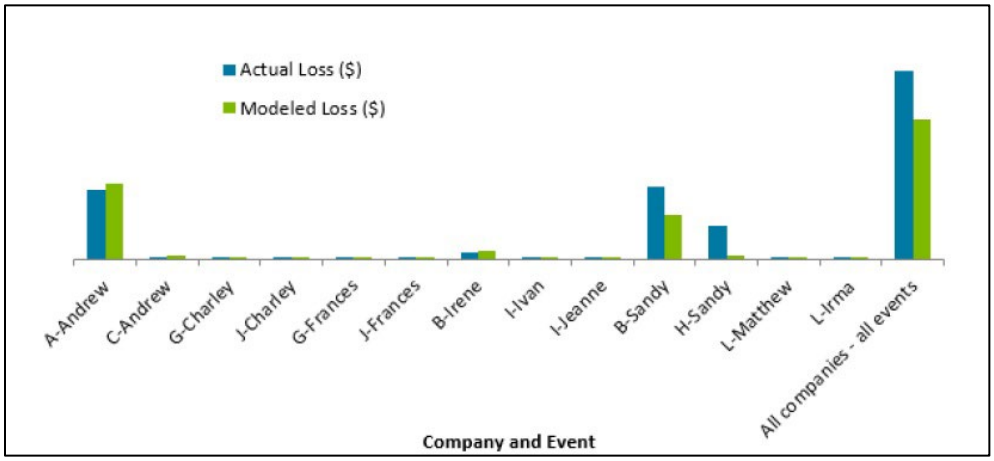

Figure 7. Actual and modeled gross loss from several different companies for residential additional living expenses (time element)

19. ***Demonstrate that loss cost relationships by construction type or vulnerability function (frame, masonry, mobile home) are consistent with actual insurance data. Include and identify the actual insurance data.***

Please see Table 7 and Table 8 in question 27 for actual versus simulated loss comparison by construction type using actual company data for various historical events.

20. ***Demonstrate that loss cost relationships among coverages, territories, and regions are consistent and reasonable.***

©2021 AIR Worldwide

The relationship between loss costs of different regions or territories is most sensitive to the frequency of hurricanes striking that region or territory and the distance from the coastline of the particular region or territory. ZIP Codes in geographic areas with historically high frequencies of hurricanes will have higher loss costs than ZIP Codes in areas of lower frequencies. Similarly, within areas of high or low frequency, ZIP Codes nearer the coastline will have higher loss costs than ZIP Codes away from the coastline.

The maps below in Figure 8 to Figure 10 show the simulated average annual loss costs by ZIP Code. The exposure assumptions are consistent with the Commission's specifications, and loss costs are related to the Coverage "A" amount (i.e. the Building Coverage). ZIP Codes along the coastline have higher loss costs than do inland ZIP Codes. Additionally, adjacent ZIP Codes are generally within one range of average loss costs reflecting the smooth transitions between ZIP Codes.

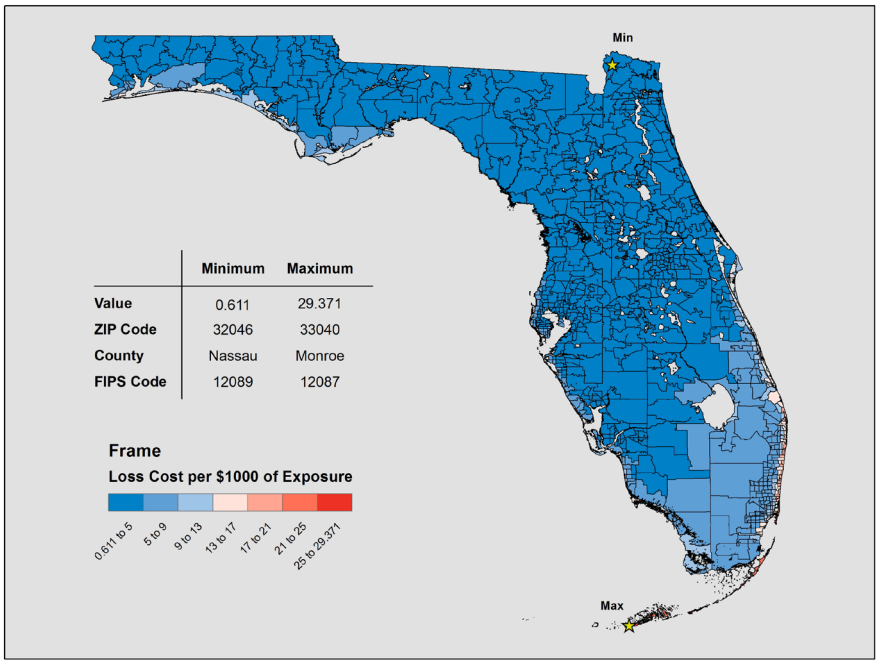

Figure 8. Loss Costs by ZIP Code for Owners Wood Frame, Zero Deductible

21. ***Describe the methods used in the model to treat deductibles (both flat and percentage), policy limits, replacement costs, and insurance-to-value when projecting loss costs.***

For any estimated mean damage, there is a probability distribution around that mean. Thus, expected damages above different deductible levels can be readily calculated. Flat dollar deductibles are applied directly while deductibles that are a percentage of the coverage amount are converted to the flat dollar equivalent and applied. The model calculates losses to replacement costs and caps losses at policy limits. Insurance-to-value is addressed by the user through the exposures entered into the replacement value and insured limit fields.

22. ***Provide an example of how insurer loss (loss net of deductible) is calculated. Discuss data or documentation used to confirm or validate the method used by the model.***

To calculate the insured loss for a location, the AIR model first obtains the local intensity then calculates the damage by using the appropriate damage functions according to the building characteristics. Finally, the financial module is used to apply the policy conditions to derive the insured loss.

The AIR damageability functions generate a mean damage ratio for a given wind speed. For any estimated mean damage ratio, there is a mixed probability distribution, $f_{\overline{D}}$, that includes finite probabilities of damage at zero and 100 percent. This representation of the damage ratio fits well with observed data. A sample distribution is shown in Figure 11 below:

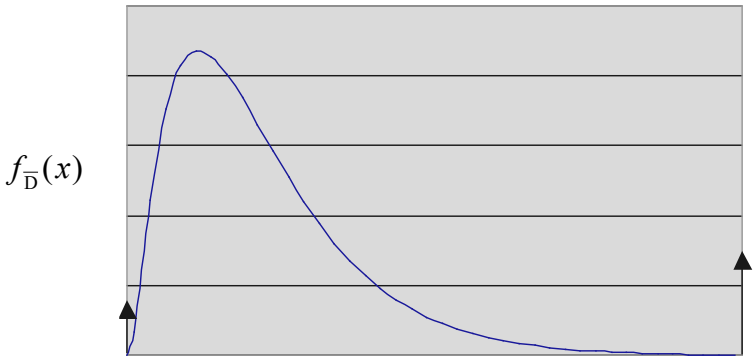

Figure 11. Probability Distribution around the Mean Damage Ratio

Thus, the effects of deductibles, coinsurance and other policy conditions can be properly calculated, as this sample insured loss calculation illustrates:

$$= \int_{x=0}^{1} f_{\overline{D}}(x)\,[\text{Coins\%} * (\min(\text{PL}, \max(0, \text{x} * \text{RV} - \text{DED}))]\,dx$$

where

Coins%	=	Coinsurance Percentage
RV	=	Replacement Value
PL	=	Policy Limit
DED	=	Deductible
x	=	Random Variable representing the Damage Ratio

©2021 AIR Worldwide

Demand surge is not applied in the formula above. However, Touchstone does apply demand surge to the ground up losses. In application, $f_{\overline{D}}(x)$ is discretized and numerical integration is used to estimate the expected insured loss.

Table 3 shows examples of how insurer losses (net of deductibles) are calculated.

Table 3. Calculating Losses Net of Deductibles

(A) Structure Value	Policy Limit	(B) Deductible	(C) Damage Ratio	(D)=(A)*(C) Zero Deductible Loss	(E) Loss Net of Deductible[2]
100,000	90,000	500	2%	2,000	1,688
100,000	90,000	500	5%	5,000	4,573

23. ***Describe the methods used in the model to calculate loss costs for contents coverage.***

The AIR Hurricane Model for the U.S. represents damages to contents separately from buildings and appurtenant structures since some policies cover contents only and some provide no contents coverage. Contents vulnerability is a function of building damage, which is in turn wind speed dependent. Figure 12 represents the relationship of mean building damage to mean contents damage used in the AIR models.

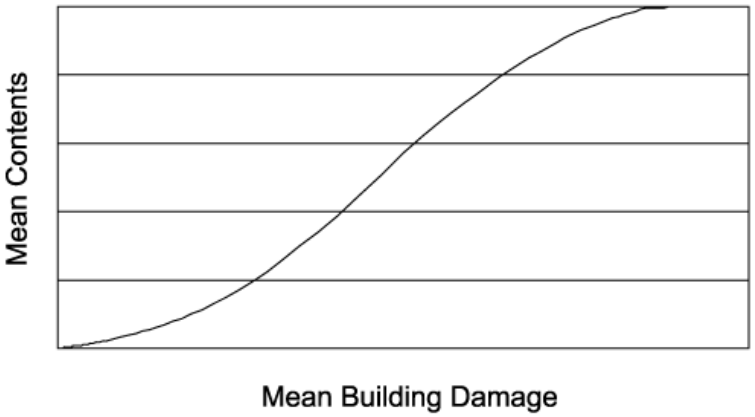

Figure 12. Contents Vulnerability Relationship

24. ***Demonstrate that loss cost relationships between structure and contents coverages are reasonable.***

The relationship among the modeled building damage ratios and modeled contents damage ratios is reasonable based on comparisons to actual loss data from client companies. See the figures provided in question 18 for validations by coverage.

25. ***Describe the methods used to develop loss cost for additional living expense coverage. State whether the model considers both direct and indirect loss to the structure. For example, direct***

[2] The calculation of the Loss Net of Deductible is based on actuarial theory of deductibles and limits as illustrated in the Expected Insured Loss equation above. The literature source is: Hogg, R.V. and Klugman, S. A., Loss Distributions, John Wiley and Sons, 1984.

©2021 AIR Worldwide

loss is for expenses paid to house policyholders in an apartment while their homes are being repaired. Indirect loss is for expenses incurred for loss of power (e.g., food spoilage).

The basic time element vulnerability functions for personal and commercial residential structures are based on the mean building damage, the time it takes to repair/reconstruct the damaged building and the estimated cost for the time element per time period. At lower wind speeds, the damage to the building is minimal and hence the time to repair is minimal. However, at higher wind speeds, resulting in significant building damage, the time it takes to repair/reconstruct could be several months. This function models losses resulting from expenses incurred while the building is being repaired/reconstructed. The model accounts for direct and indirect losses to the extent that they are in the validation data.

Figure 13 reflects the relationship between repair/reconstruction time and the mean building damage. The time element loss estimates have been validated using actual client company loss data.

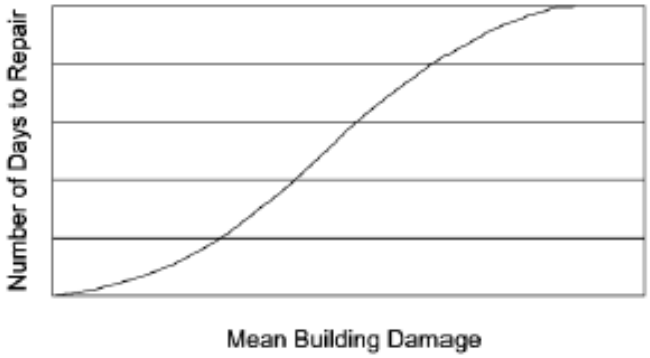

Figure 13. Time Element Vulnerability Relationships

26. ***State the minimum threshold at which additional living expense loss is calculated (e.g., loss is estimated for structure damage greater than 20% or only for category 3, 4, 5 events). Provide documentation of validation test results to verify the approach used.***

Additional living expense (ALE) loss is a function of mean building damage ratio, which is non-zero beginning at a minimum wind speed of 40 mph.

AIR validates the model's time element vulnerability functions at many levels, from an aggregate industry level loss perspective down to claims at individual policies or locations. When the client provides exposure information related to time element coverage, AIR will supply the provided information to the model, including policy characteristics and terms. The subsequent claims data corresponding to the exposure may or may not include loss information which contains the application of policy characteristics and terms. AIR will compare the claims data, based on the knowledge of whether the values provided include policy conditions, with modeled output that contains both loss information before the application of policy conditions (ground-up) and after the application of policy terms (gross). This process is used for time element loss validation in the same way that is used for building vulnerability validation.

Validation data of the actual and simulated damages for Coverage D, across several company and historical events can be seen in Figure 7.

©2021 AIR Worldwide

27. ***Provide all comparisons of actual exposures and actual losses to modeled exposures and modeled losses for the model. These comparisons must be provided by line of insurance, construction type, policy coverage, county or other level of similar detail. Total exposure represents the total amount of insured values in the area affected by the hurricane. This would include exposures for policies that did not have a loss. If this is not available, use exposures for only those policies that had a loss. Specify which was used. Specify the name of the hurricane event for each comparison. List any data sources excluded from validation and the reason for excluding the data.***

Table 4 through Table 9 shows how AIR's simulated losses compare, in total and by coverage and construction, to the losses of specific client companies for key storms including 2004 and 2005 storms: Hurricanes Andrew, Charley, Erin, Frances, Ivan, Jeanne, Wilma, and Katrina. Note that the losses in the tables have been scaled to protect the identity of the companies.

28. ***Discuss in detail and provide summaries of all validation work that has been performed on the model to confirm that the components of the model are accurate in their roles necessary to project Florida loss costs. This includes damage surveys, detailed claims data collected and analyzed and damage ratios by wind speed and duration of damaging winds among other things.***

AIR engineers and scientists have surveyed all significant loss causing events since Hugo in 1989, including the notable events such as Andrew, Fran, Georges, Floyd, Charley, Frances, Ivan, Jeanne, Dennis, Katrina, Rita, Wilma, Gustav, Ike, Irene, Sandy, Matthew, Harvey, Irma, and most recently, Florence and Michael in 2018. Additionally, AIR engineers and scientists have surveyed damage in the aftermath of major storms outside of the mainland U.S., including Hurricane Floyd in the Bahamas, Hurricane Fabian in Bermuda, Tropical Cyclone Yasi in Australia, Hurricane Irene in the Caribbean, Tropical Storm Iselle in Hawaii, Hurricane Gonzalo in Bermuda, and Hurricane Maria in Puerto Rico. These surveys improve our understanding of the response of structures to winds, including damage mechanisms. Such damage investigations provide, for example, information on the relative vulnerability of various construction types and building components used in the development and validation of the vulnerability relationships.

Based on AIR's damage investigations, buildings can generally be classified as "engineered" or "non-engineered" structures. Most residential dwellings are generally classified as non-engineered. A typical example is a wood frame single-family dwelling, a construction that may not have received much attention from a structural engineer. Most commercial structures, often built in accordance with building codes and under the supervision of a structural engineer, are classified as engineered structures. A typical example of an engineered structure is a high-rise reinforced concrete building.

©2021 AIR Worldwide

In general, an engineered building is more wind resistant than a non-engineered building. The 2004 and 2005 post-disaster surveys conducted by AIR engineers and scientists indicate that low-rise commercial and residential-commercial wood frame and masonry buildings—that do not get as much engineering attention as the high-rise buildings—have similar vulnerability as their residential counterparts. Recent damage surveys have also indicated that the year-built of a residential dwelling provides important information in determining its vulnerability. Newly-built buildings were observed to perform better than their older counterpart buildings.

Wind damage primarily affects non-structural elements, such as windows, cladding or other components of the building envelope. Field surveys indicate that the initial point of failure wood-framed homes often occurs at the roof, likely due to the improper fastening of the roof covering, sheathing, support structure and building frame. Other roof system failures could be attributed to the lifting and peeling of metal edge flashings, and from here additional damage will propagate. Uplift of the roof edges allows the wind to penetrate underneath the roof membrane, resulting in a pressure rise beneath the membrane and removal of the roof covering. At high wind speeds, the integrity of the entire structure can be compromised, particularly in cases where the roof provides lateral stability by supporting the tops of the building's walls.

Thus, three damage regimes can be identified for residential buildings: a) the low damage regime corresponding to wind speeds of less than about 90 mph, where damage is limited to roof covering and cladding, b) the medium damage regime where damage propagates to roof sheathing, connections and openings and c) the catastrophic damage regime corresponding to wind speeds in excess of 130 mph, where the roof framing is severely damaged, resulting in lateral instability of walls causing further collapse and complete destruction of the building. In the case of engineered buildings, damage typically occurs to non-structural components like mechanical equipment, roofing, cladding and windows; complete structural collapse is extremely rare.

In certain parts of the United States, masonry building systems are the prevalent construction method for residential and commercial residential construction. When masonry is used as the exterior wall material, the walls are normally constructed to full height and then wood floors and the roof are framed into the masonry. Damage investigations have confirmed that such construction results in continuous exterior walls and thus a stronger structural frame, resulting in exterior walls that are more resistant to winds and windborne debris impacts as compared to wood frame buildings.

While exploring the damage caused by Hurricane Georges (1998) and Tropical Storm Frances (1998), AIR engineers validated the effects of wind duration on damage estimation, a fundamental component of the AIR vulnerability model. Damage resulting from a slower moving (longer duration) storm can be higher because of the cumulative effects of wind.

Information obtained from post-disaster damage investigations, has been incorporated in the development and validation of the vulnerability model.

29. ***State whether or not the model includes explicit consideration of duration. If so, explain why. If not, explain why not.***

Yes, the AIR Hurricane Model for the U.S. includes the effects of hurricane duration using a stepwise procedure. For each given location, for the first time period during the storm when the sustained winds exceed 40 mph, the damage occurring during this time period is estimated, and the remaining undamaged portion of the exposure is determined. For each successive time period

©2021 AIR Worldwide

where the winds exceed 40 mph, the same procedure is followed, and the remaining undamaged portion is subjected to damage in each time interval. In this manner, longer duration storms having the same maximum speed as shorter duration storms will show accumulation of additional damage, as has been reflected in damage surveys. The AIR Hurricane Model for the U.S. team members presented a well-received paper on duration effects and how to model them at the 11th America's Conference on Wind Engineering in Puerto Rico in June 2009.

30. ***Provide copies of all independent peer reviews that have been performed of the model (include Bests, Standard and Poor's, Moody, etc. as applicable).***

AIR models have undergone extensive external review by rating agencies and by independent scientists.

In 1986 Walter A. Lyons, Ph.D. was contracted by the E.W. Blanch Company to review the AIR hurricane simulation model. During 1996 and 1997, Duff & Phelps, Fitch, Moody's and Standard & Poors all reviewed AIR's US Hurricane Model in conjunction with their rating of the USAA catastrophe bond.

Following are the independent peer reviews that have been performed on components of the AIR model, along with summaries of the more recent reviews:

Meteorology—Review by Dr. Walter Lyons in 1986; by Dr. John Freeman in 1994; and by Dr. Kerry Emanuel, Dr. Peter Black, and Dr. Robb Contreras in 2010.

Vulnerability—Reviewed by Dr. Joseph Minor, P.E. in 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, and 2009; by Dr. Carol Friedland and Dr. Marc Levitan in 2010; and by Dr. Carol Friedland in 2012, 2014, 2016, 2018 and 2020.

Computer Science—Reviewed by Dr. Mark Wolfskehl in 2002; by Dr. John Kam in 2003, 2004, and 2005; by internal auditor Tyler Maxwell in 2009; by Angelo Jeyarajan in 2014; by Narges Pourghasemi in 2007, 2008, 2010, 2012, 2016, 2018 and 2020.

Actuarial Science—Reviewed by John Rollins, FCAS, MAAA in 2010 and in 2012.

The model evaluation of Walter Lyons is attached as Attachment E. The curriculum vitae of Dr. Carol Friedland, Ms. Narges Pourghasemi and their model evaluations are attached as Attachment F1 and F2 and Attachment G1 and G2 respectively. The curriculum vitae of Peter Black, Robb Contreras, and Kerry Emanuel are attached as Attachment H[3]. The evaluation of the Residential Re Ltd. Bond Issue by Moody's is attached as Attachment I.

31. ***Supply copies of all documents and graphical comparisons that support the independence of wind speed and damage models.***

AIR performs separate and independent validations for wind speed and damage ratio.

[3] The model evaluations by Dr. Black, Dr. Contreras, and Dr. Emanuel are trade secret information

Wind Speed Validation

Extensive comparisons have been performed between model generated wind speeds and observations to check for spatial extent of the winds and their amplitude. Observational data has been gathered from NHC's Tropical Cyclone Reports as well as other data sources, like HURDAT2, dropsonde data, Texas Tech high-resolution data and various published reports, for 36 historical storms (11 Florida storms). Comparisons performed include scatter plots of model winds versus observed winds, wind distribution against distance from the eye and storm model footprint (hourly or over storm lifetime) versus point wind observations, h*Wind data (Landsea et al., 2004; Powell et al., 1998) or DeMaria radii (Demuth et al., 2006). Mean statistics were computed for wind differences over all amplitudes or at different wind bands. Below in Table 10 we include a set of validation tests performed for Hurricane Andrew (1992).

Table 10. Validation Tests Performed for Hurricane Andrew (1992)

Storm	Sample Size	ExplVar (%)	Correlation	MBE (mph)
Andrew	31	82.81	0.91	5.40

where MBE = Mean Bias Error = Mean(ModelWind) - Mean(ObsWind)

Additionally, Figure 14 and Figure 15 demonstrate that the consistency between the distribution of model-generated wind speeds for Hurricane Andrew and the distribution of its observed wind speeds.

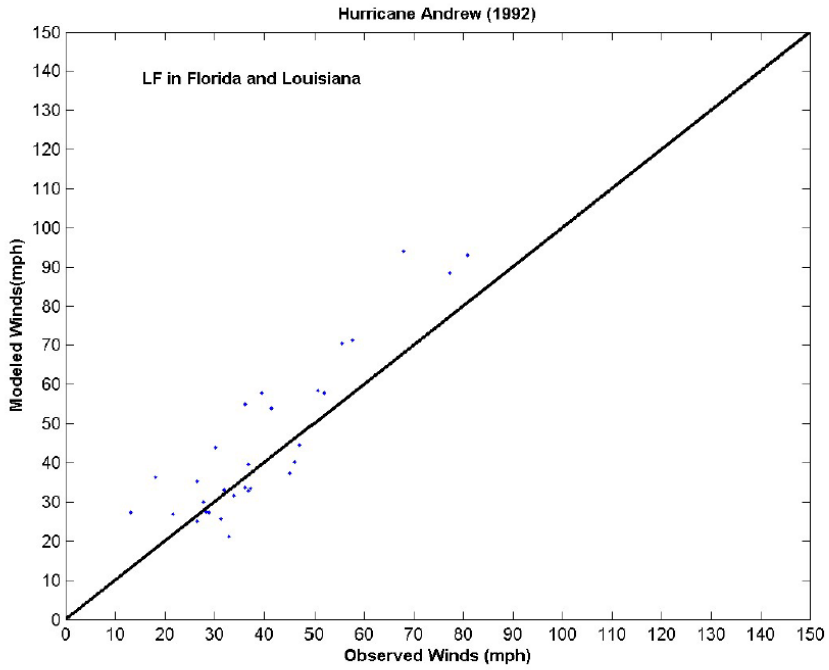

Figure 14. Modeled Versus Observed Surface Winds for Hurricane Andrew (1992)

©2021 AIR Worldwide

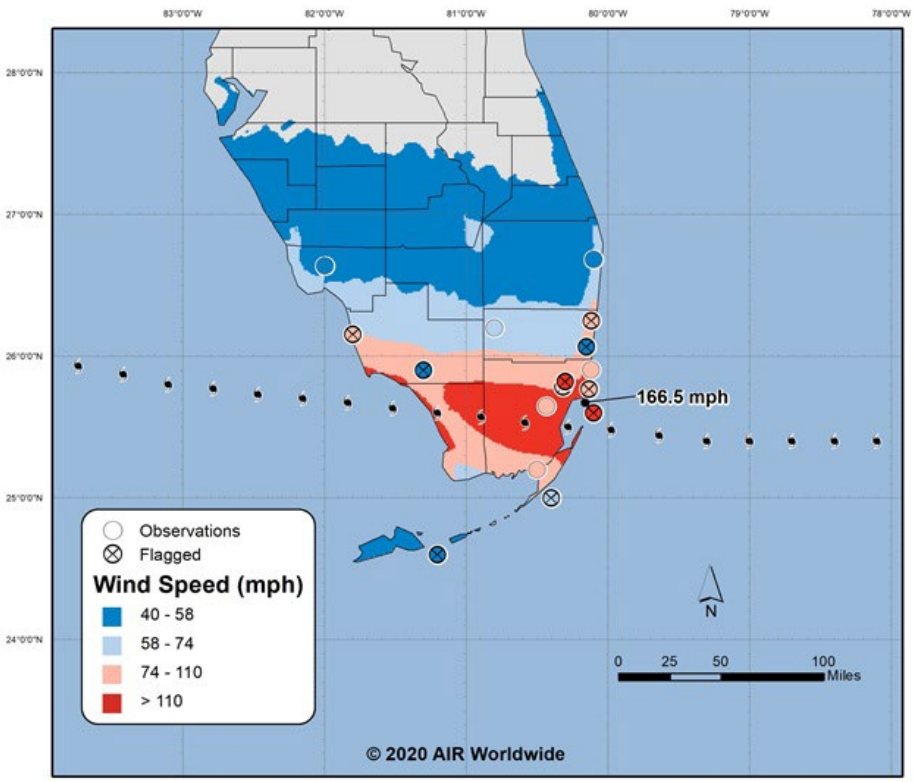

Figure 15. Hurricane Andrew's Maximum Wind Footprint (Colors) Overlaid With Station Wind

The work performed as part of the Florida Commission filing has also confirmed that the wind speed calculation works as intended. Using sample input characteristics on central pressure, radius of maximum winds, forward speed, and far field pressure provided by the Commission, AIR generated hourly wind speed measurements over a rectangular grid covering locations in Southern Florida. The results generated in such a study, and the subsequent sensitivity and uncertainty analyses performed, helped confirm the validity of the calculation.

Damage Function Validation

The AIR damage functions have been extensively validated using detailed actual loss data provided by a number of clients for various storms. Typically, the loss data is available by five-digit ZIP Code. Validation was performed by comparing simulated and actual losses for client companies by state and/or county and by line of business for a number of hurricanes as shown in question 27.

The detailed data available to AIR has enabled the fine-tuning of damage ratios by construction class and by coverage type as well as by wind speed. Examples of the comparison between actual loss data and the AIR vulnerability functions are shown in Figure 16. Additionally, Figure 5 through Figure 7 included in responses above also demonstrate the loss validations performed by AIR using actual company data.

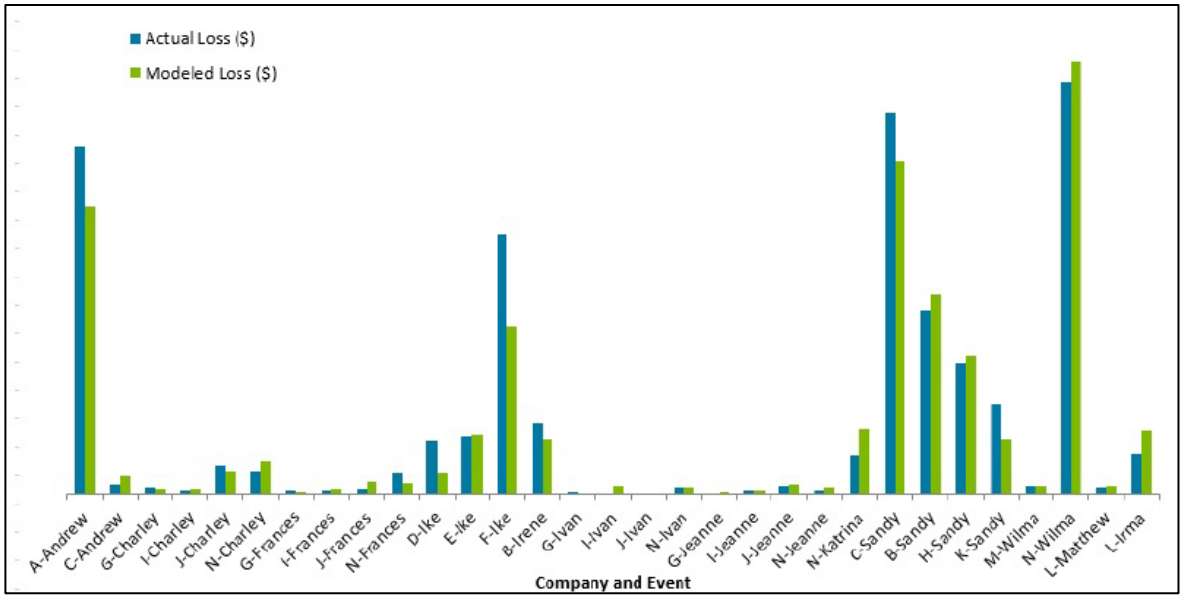

Figure 16. Actual vs. Simulated Losses for Personal and Commercial Residential Lines of Business

32. *Provide a complete discussion of the independence of track angle and forward speed.*

We have examined the correlation between track angle and forward speed using historical data for the period 1900-2008. The historical data do not show a statistically significant relationship between the two variables. Because of this, we do not assume dependence between the two variables in the model.

33. *Provide a complete discussion of the (1) spatial consistency of the reduction factor used to convert between gradient and surface wind speeds and (2) the treatment of uncertainties in this conversion.*

The model first computes the maximum wind at upper levels and then brings this wind to the surface level (10 meters) via a conversion factor. This factor, the Gradient Wind Reduction Factor (GWRF) described in response to question 7, represents a model parameter which varies stochastically by storm, and for a particular storm varies by location as a function of the PWF and distance from Rmax. The Radial Adjustment Function (RAF) adjusts the GWRF as a function of distance to the eyewall (r) and hours after landfall. Because Rmax varies with time, the RAF is also variable in time for a given storm. The GWRF is independent of storm intensity.

Justification for varying GWRF with distance from the storm center is based on analyses of the spatial distribution of GWRF using operational dropsonde data (data is publicly available from NOAA/AOML/Hurricane Research Division in Miami, Florida). Furthermore, these analyses combined with results from published literature (Franklin et al., 2003; Powell et al., 2009) justify varying GWRF by storm. The mean value of the stochastically drawn GWRF, the distribution about the mean, and the form of the RAF have been developed based on these data and research.

©2021 AIR Worldwide

34. ***Demonstrate why you do or do not believe that "open ocean" track distributions provide reasonable distributions of storm landfall frequency. Demonstrate how you have ensured that the landfall distribution is representative of the historical set. Demonstrate how bypassing storms are generated and treated in the model, including documentation in detail of how the model assures that an event is well defined.***

1) Because the "open ocean" track distributions would not be sufficient to generate an accurate landfall distribution for the coast of Florida, the stochastic events in the AIR model are developed by first selecting a landfall location using a probability distribution, which is based on the number of historical landfalls per approximately 50 nautical mile segment along the coast, then generating the full event tracks by joining the landfall-based paths back to corresponding storm geneses and tracks in the open ocean.

2) The HURDAT2 database provides data at synoptic times, with the inclusion of data at non-synoptic times for critical events of a storm lifetime (time of landfall, maximum intensity, etc.). The dataset allows for a resolution that is sufficient to capture the evolution of each storm across the Atlantic basin.

   The inclusion of the landfall point for reanalyzed storms as well as recent storms provides the model the necessary information to appropriately change the storm characteristics once it moves inland. In the case of storms that have not yet been reanalyzed, the model uses detailed landfall information available in Appendix A in NOAA Technical Memorandum NWS NHC-6, Tropical Cyclone Reports from NHC (available at http://www.nhc.noaa.gov/pastall.shtml), peer-reviewed publications, UNISYS, Extended Best Track Dataset, and NOAA Technical Reports NWS-23 (Schwerdt et al., 1979) and NWS-38 to generate storm characteristics at landfall.

   The analysis of the data shows that first-order Markov models are appropriate for track direction and forward speed. Higher order dependence present in the central pressure along the track is represented using a second-order autoregressive time series model. The parameters of these models are estimated using a procedure that captures the spatial variability in the behavior of the storms in different parts of the Atlantic basin.

   The landfall information, including locational frequency and storm intensity, is also used to eliminate tropical storm landfalls and generate post-landfall hurricane tracks. The Atlantic basin-wide tracks are integrated with the post-landfall hurricane tracks using a spline smoothing technique that ensures consistency in intensity, radius of maximum winds and storm heading across the tracks. The methodology produces realistic tracks that resemble the full range of diverse storm tracks that have been observed historically across the Atlantic basin and the U.S. mainland.

3) The AIR model generates bypassing storms as well as landfalling storms through a track generation procedure that follows each simulated hurricane from the time of its inception until its dissipation. A bypassing hurricane is one that does not make landfall in Florida as a hurricane but does cause damaging winds over land.

   An event, or simulated hurricane in the context of the AIR Hurricane Model for the U.S., is a landfalling hurricane or a hurricane that bypasses the coast of Florida. The results of the simulation are carefully checked to ensure that the simulated frequency of landfalling and bypassing storms is consistent with the historical frequency of these storms during the period 1900-2018. In addition,

©2021 AIR Worldwide

the simulated tracks are carefully checked to ensure that each event looks realistic and is well defined in the model.

35. ***Do you reset extreme values so as not to be inconsistent with the historical record? If so, which storm parameters are most often affected? How does this impact the uncertainty calculations in the model?***

To ensure that the simulated events are consistent with the historical record, the AIR model imposes bounds on the modeled probability distributions used to represent hurricane intensity, forward speed, radius of radii for maximum winds, and track angle. Extreme values that fall outside the bounds are typically re-sampled to arrive at distributions that are consistent accepted scientific literature.

For central pressure, any value below 884 millibars is reset to a value at or just above 884. The frequency of adjusting extremes is a function of the shape and variance of the probability distributions used for each storm parameter. The radius of maximum winds is simulated using a regression model with central pressure and latitude used as input variables and with Normally distributed noise added to generate a distribution around the mean. Bounds that depend on central pressure are imposed to capture the fact that the radius of intense hurricanes tends to be smaller than that of weaker hurricanes. The bounds are most often imposed for intense storms, and inclusion of the bounds eliminates storms that would not be physically realistic, thereby reducing the uncertainty in the model output.

36. ***Discuss in detail how distance from the coast impacts intensity.***

Distance from the coast is not a variable that enters the model wind calculation. However, in many cases, the distance from the coast is well correlated with the time after landfall, which is an important variable in computing the storm decay after landfall.

Once over land, the hurricane moves away from its source of energy, i.e., warm ocean water. As a result, the eye "fills" and the central pressure increases (winds degrade) with increasing time after landfall. The filling functions give the reduction in the pressure deficit (i.e. the difference between the central storm pressure and the pressure at the periphery of the storm) as a function of time since landfall. A faster forward speed will cause a hurricane to maintain its intensity further inland than a slow-moving storm with the same initial intensity (pressure deficit).

The functional form of the pressure deficit decay function is:

$$\Delta P_t = \left[P_P - P_{eyeLF} \times \left(1 + LF_{offset} \times t^{C_1}\right)\right] \times e^{-C_2 t}$$

where:

ΔP_t	= Pressure deficit at a given time after landfall
P_p	= Atmospheric pressure at the periphery of the storm
$P_{eye\ lf}$	= Central pressure of the storm at landfall
LF_{offset}	= Initial reduction of the pressure deficit at landfall
T	= Time after landfall in hours
C_1	= Time shaping constant
C_2	= Exponential decay rate constant

Note that the function parameters vary by coastal region and smoothing algorithms are applied such that there is no sudden jump between regions.

©2021 AIR Worldwide

This formulation is justified as it computes the necessary change in intensity parameter relevant to the model (i.e. change in central pressure as a function of time). The hurricane filling functions provide reliable weakening rates for the state of Florida and neighboring states and are consistent with inland decay functions, such as those developed by Kaplan and DeMaria (1995), further justifying their use.

Perturbations to the model's standard filling relationships are allowed to account for the low probability of tropical cyclones undergoing an episodic period of re-intensification after landfall. The implementation of such filling perturbations is motivated by the work of Bosart and Lackmann (1995), Hart and Evans (2001) and Arndt et al. (2009), and is based on observed historical storms. The procedure is only applied to storms which would likely undergo a transitioning phase and eventually reach 42° latitude. Within the state of Florida, such perturbations occur only in a very small number of stochastic events.

37. ***Prepare graphical depictions of hurricane characteristics as used in the model.***

Describe and justify:

a. ***The data set basis for the fitted distributions.***

b. ***The modeled dependencies among correlated characteristics in the wind field component and how they are represented.***

c. ***Your treatment of the asymmetric nature of hurricanes.***

d. ***The fitting methods used and any smoothing techniques employed.***

The primary model variables in the AIR Hurricane Model for the U.S. along with their associate probability distributions were described in question 14 above. These variables include:

- Annual landfall frequency
- Central pressure at landfall
- Radius of maximum winds
- Forward speed
- Landfall angle

The AIR Hurricane Model for the U.S. uses a Negative Binomial distribution to generate the number of hurricane landfalls per year. The graph below shows the actual historical data from 1900 to 2018 along with the modeled distribution for the entire U.S. coastline. The modeled distribution fits the historical data very well (see Figure 17). Also, for the state of Florida as a whole, the modeled average annual frequency of 0.61 landfalling hurricanes per year agrees with the average annual historical frequency of 0.61 landfalling hurricanes per year. We make no other assumptions as to future hurricane activity.

©2021 AIR Worldwide

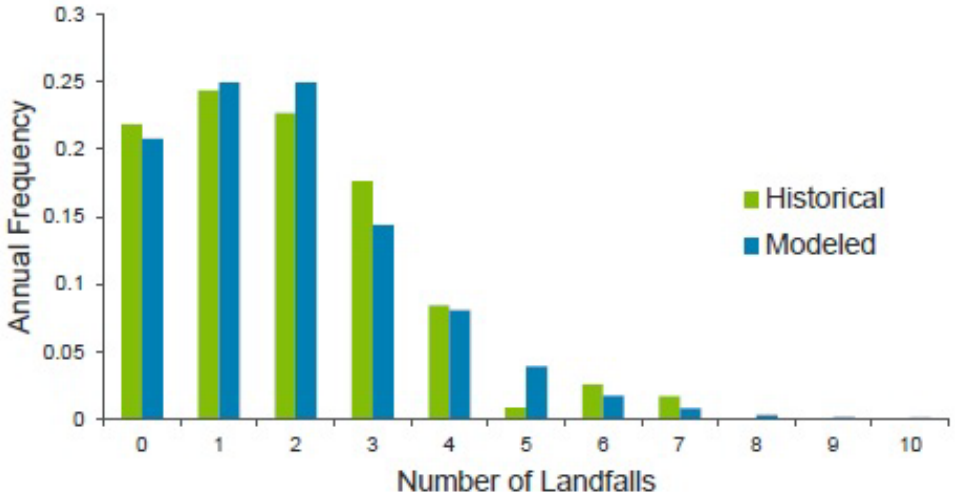

Figure 17. Historical and Modeled U.S. Annual Landfall Probability Distributions, 1900-2018

Graphs related to other model variables are available for review.

Describe and justify:

a. The data set basis for the fitted distributions.

AIR uses the historical information available from both HURDAT and HURDAT2 from year 1900 to develop probability distributions for central pressure, coastal location, and Florida storm frequency. Data for model variables not available from the two databases are derived from NWS-23, NWS-38, preliminary reports, and other sources.

b. The modeled dependencies among correlated characteristics in the wind field component and how they are represented.

All existing modeled dependencies among hurricane parameters are in line with observations. Most hurricane parameters are considered independent of one another. The following variables are dependent on latitude:

- Central pressure
- Forward speed
- Storm heading
- Air density coefficient
- Coriolis parameter
- Peripheral pressure
- Filling rate

The air density coefficient, Coriolis parameter, and peripheral pressure are direct functions of latitude; the latitudinal dependence for the rest of the parameters is modeled by coastal segment.

©2021 AIR Worldwide

The radius of maximum winds is represented using a regression model of the form $R_{max} = f(Cp, latitude) + \varepsilon$ (error term).

The wind field radial profile is based on the formulation introduced by Willoughby et al. (2006) and depends on Rmax, Vmax and latitude as well as distance from the eye. The wind increases as a power of radius inside the eye and it decays exponentially outside the eye, following a smooth transition between the two regions.

The direction from the center position is included in the asymmetry term, which is proportional to the forward speed of the storm and the cosine of the angle between the wind direction and the storm moving direction.

The adjustment to the gradient wind reduction factor (used to convert upper level winds to surface winds) is dependent on the distance from the eye and an additional factor associated with each storm called the peak weighting factor (used to reflect the vertical slant in the hurricane eye and derived from the research of Powell et al. (2009)). The gradient wind reduction factor and the peak weighting factor are generated jointly from a bounded bivariate normal distribution.

Also entering the wind calculation are the friction and gust factors, both depending on the effective roughness length which in turn is determined from the land use land cover data, and a maritime adjustment (derived from the research of Powell et al., 2003) which is dependent on the windspeed.

c. Your treatment of the asymmetric nature of hurricanes.

The term that resolves the asymmetric structure of the hurricane is a function of the translation speed of the storm and the angle between the wind direction and the storm moving direction. This contribution (expressed as a wind in miles per hour) is *added* to the total wind associated with the storm.

d. The fitting methods used and any smoothing techniques employed.

The maximum likelihood method is used to estimate the parameters of the probability distributions used for minimum central pressure, radius of maximum winds, and forward speed. To capture spatial variability in storm characteristics, the U.S. coastline is divided into 100-mile coastal segments and the parameters are estimated separately for each 100-mile segment. To reduce sampling variability and achieve a smooth transition from segment to segment, the data are pooled spatially so that data from 400 miles of coastline are used to estimate the parameters for each 100-mile segment. The pooling of the data is done symmetrically around each segment of interest.

38. ***Provide explanations and documentation that demonstrate that the hurricane intensity at landfall is consistent with the Saffir-Simpson wind range for the stochastic storm set.***

The upper limits of wind speeds in the AIR Hurricane Model for the U.S. conform to the limits as defined by the Saffir-Simpson scale:

©2021 AIR Worldwide

Table 11. Upper Limits of Wind Speeds in the AIR Hurricane Model for the U.S.

Saffir-Simpson Category	Upper Limit Wind Speed (mph)
1	95
2	110
3	129
4	156
5	171

Please note that the upper wind speed limit provided in Table 11 is the idealized maximum over water wind speed simulated for all events in the catalog. The AIR model uses maximum 1-minute sustained 10-meter windspeed when defining hurricane landfall intensity for both the Base Hurricane Storm Set and the modeled windspeeds. Please note that the model technically does not have an upper wind speed bound for Cat 5 events. Instead, the model has a lower bound on central pressure that resets any values below 884 mb to a value at or just above 884 mb, which is the lowest observed central pressure observed in history.

39. ***Describe and support the method of selecting stochastic storm tracks.***

The methodology used to generate storm tracks is based on the information available in the National Hurricane Center HURDAT2 database for the period 1900-2007. This database provides track information for more than 1,000 North Atlantic storms at six-hour time intervals. Time series techniques have been used to determine the dependence structure present in key model variables from one time period to the next. Time series models that describe the dependence in the historical data are used in the generation of simulated tracks. For example, a first-order Markov model with transition probabilities estimated from the historical data is used to generate changes in track direction of simulated storms. An illustration of the procedure is provided below. The storm tracks generated using this approach are realistic and resemble storm tracks that have been observed for historical storms.

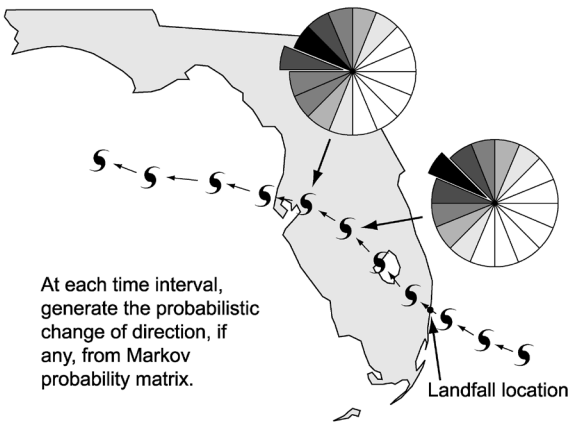

Figure 18. Storm Track Generation

AIR uses the event generation component of the model to simulate 50,000 years of potential hurricane activity.

©2021 AIR Worldwide

40. ***Describe and support the method of selecting storm track strike intervals. If strike locations are on a discrete set, show the landfall points for major metropolitan areas in Florida.***

To determine hurricane probabilities along the coast of Florida, the actual number of hurricane occurrences is tabulated for approximately 50-nautical-mile segments. For intensity distributions, 100-nautical-mile segments are used (i.e. consecutive 50-nautical-mile segments). The number of occurrences for each segment is then smoothed by setting it equal to a weighted average of the landfall counts for each segment and the surrounding segments. The following averaging formula is employed:

$$F_i = \frac{\sum_{n=-3}^{3} W_n \cdot C_{i+n}}{\sum_{n=-3}^{3} W_n}$$

where C_i = the number of historical hurricane occurrences for the ith segment

F_i = the smoothed frequency value for the ith segment

W_n = 0.30, 0.22, 0.12, and 0.01, for n = 0, ± 1, ± 2, and ± 3, respectively

The smoothing is based on a procedure well-documented in the literature (e.g., NOAA Technical Report NWS-38, page 75). The historical hurricane frequency distribution by intensity for each 100-mile coastal segment is shown in Figures 19 and 20.

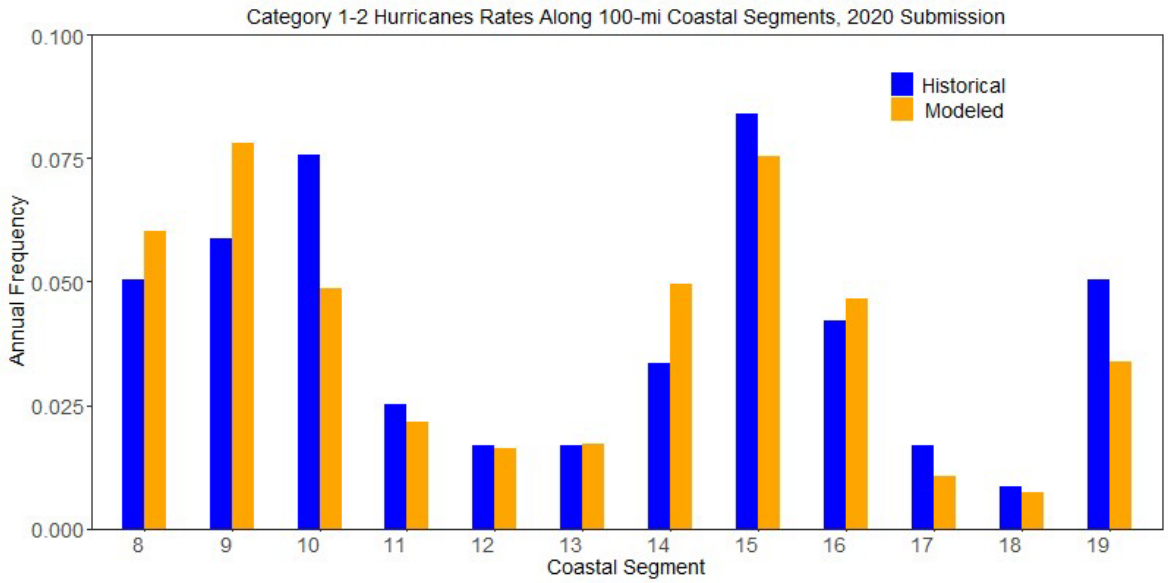

Figure 19. Historical Category 1-2 Hurricane Frequency by Coastal Segment, 1900-2020

©2021 AIR Worldwide

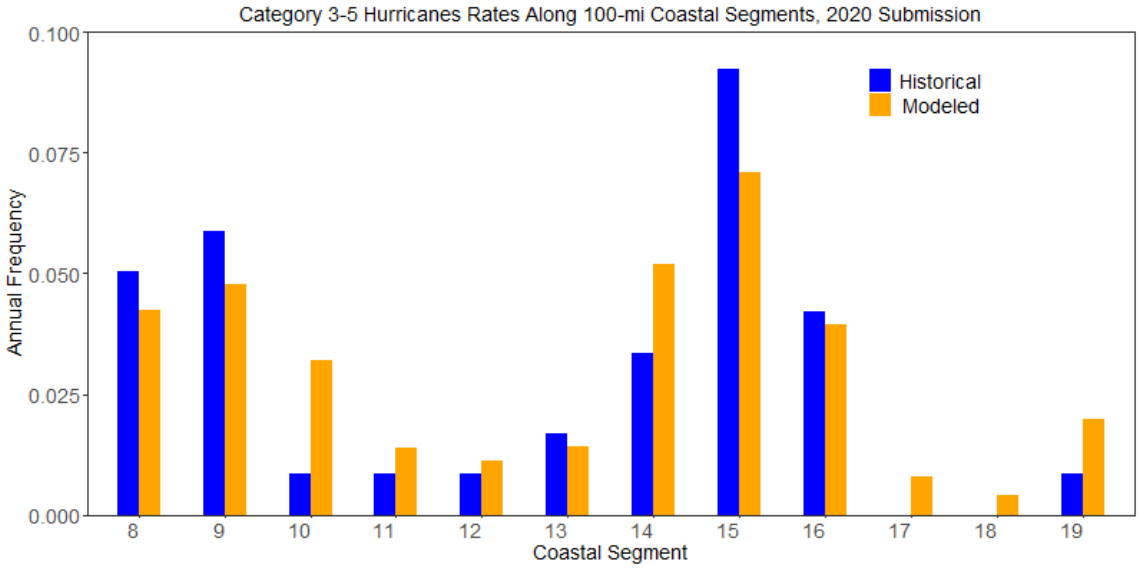

Figure 20. Historical Category 3-5 Hurricane Frequency by Coastal Segment, 1900-2020

41. ***Besides those variables identified in the M-5 disclosures (Meteorological Standard Number 5 of the Florida Commission on Hurricane Loss Projection Methodology), identify other variables in the model that affect over land wind speed estimation.***

No other variables affect over land wind speed estimation in the model.

42. ***Describe the representation of land friction effects in the model. Describe the variation in decay rate over land used in the model. Provide maps depicting land friction effects.***

The method used by AIR to model the effects of land friction on wind speeds is based on scientific methods and provides realistic wind speed transitions between adjacent ZIP Codes, counties, and territories. The magnitude of the friction coefficients is consistent with the accepted scientific literature. Typical references include Simiu and Scanlan "Wind Effects on Structures", N. Cook "The Designers Guide to Wind Loading of Building Structures. Part 1" and ESDU Engineering Sciences Data "Wind Engineering."

In the AIR model, the initial step in calculating the friction coefficient for each point of interest is to obtain an estimate of the surface roughness at the site. At ground level, horizontal drag forces induced by the surface roughness are exerted on the wind flow, causing retardation of the wind near the ground. The surface roughness is estimated based on the latest digital USGS land use/land cover data. The land use/land cover categories vary from urban or built-up land, to agricultural land, to forest land or wetlands, to water. Each terrain type has a different "roughness value" that will lead to different frictional effects on wind speeds. In general, the rougher the terrain the larger the frictional effect on wind speeds. The magnitudes of the friction coefficients in the AIR method are consistent with accepted scientific literature and empirical hurricane wind speed data.

©2021 AIR Worldwide

It is important to note that as a hurricane travels inland and encounters different types of terrain, the hurricane wind speeds do not adjust immediately upon experiencing a new terrain type. In practice, the wind has to blow over a certain length, or fetch, before the boundary layer is in equilibrium with the underlying surface, i.e., the variation of wind speed with height does not change as the fetch of the upwind uniform terrain increases. Downwind of a change in terrain roughness, such as the edge of an urban area, a new internal boundary layer begins to grow. Within this new layer the flow is not in equilibrium and the wind profile changes as distance increases. The wind profile change is modeled by using a function that varies the upwind friction coefficient to the equilibrium or fully developed friction factor over the appropriate fetch. The transition is consistent with the accepted scientific literature and the actual available hurricane wind speed data.

In the model the wind computation uses directional friction factors. At every time step, the wind direction at a given location is evaluated and the respective directional factor is applied to the wind value. Figure 21 below shows friction factors for the Florida Panhandle for winds coming from the South direction.

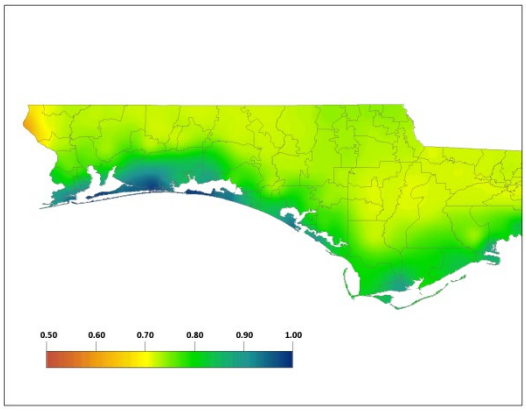

Figure 21. Friction Factors for Winds Coming From the South

The variation in decay rate (or filling) over land has been discussed under question 36. The filling functions give the reduction in the pressure deficit (i.e. the difference between the central storm pressure and the pressure at the periphery of the storm) as a function of time after landfall. The function parameters vary by coastal region and the resulting filling functions are consistent with observations as well as other inland decay functions, such as those developed by Kaplan and DeMaria (1995).

43. ***Justify the relationships between central pressure and both radius of maximum winds and radius of hurricane force winds.***

The probability distribution for radius of maximum winds (Rmax) is modeled using a regression model of the form:

$$R_{max} = f(\text{cp, latitude}) + \varepsilon\ ,$$

©2021 AIR Worldwide

where f(Cp, latitude) represents the mean of Rmax for given values of central pressure and latitude. The error term, ε, is assumed to be normally distributed. The parameters in this regression model are estimated using data available in NOAA Technical Report NWS-38, the HURDAT2 Reanalysis Project, and the DeMaria Extended Best Track Dataset (EBTRK). The final distribution is truncated using limits that depend on central pressure and are consistent with the range of historically observed values. Rmax also varies after landfall, following an autoregressive model.

A study by Kimball and Mulekar (2004[4]) and an earlier study by Weatherford and Gray (1988[5]) do not reveal any relationship between storm intensity and the radius of hurricane force winds.

44. ***Does your model generally underestimate losses for low wind speeds and overestimate losses for high wind speeds? If it does, explain how this can be acceptable. If you assert that it does not, supply convincing evidence of the independence of wind speed and the accuracy of damage estimates.***

AIR believes that the model provides an unbiased estimation of losses across the range of wind speeds. Charts provided in question 18 and tables in question 27 show that simulated mean damage ratios are consistent with actual mean damage ratios. The effect of uncertainty in damageability as well as in local intensity is treated by considering probability distributions around the model damage functions. For a given wind speed, the AIR models explicitly include a distribution around the mean damage to account for the possibility that the actual damage may be higher (or lower) than the mean damage.

45. ***Provide a listing of any papers, reports, and studies used in the development of the vulnerability functions.***

A list of papers, reports and studies used in the development of vulnerability functions has been provided in Standard G-1 Disclosure 6 of AIR's model submission to the FCHLPM (see page 27 of the submission doc: https://www.sbafla.com/methodology/Portals/Methodology/ModelSubmissions/2021/AIR_2019_FCHLPM_Submission_20210519.pdf?ver=2021-06-17-103335-633)

46. ***Justify the construction types and characteristics used, and provide validation of the range and direction of the variations in damage.***

The range and direction of the variations in damage and supporting validation data is available for review.

47. ***Document and justify all modifications to the vulnerability functions due to building codes and their enforcement.***

The AIR damage functions incorporate the results of well-documented engineering studies, tests, and structural calculations. They also reflect the relative effectiveness and enforcement of local

[4] Kimball, Sytske K and Madhuri S. Mulekar, 2004: 115-Year Climatology of North Atlantic Tropical Cyclones. Part I: Size Parameters. Journal of Climate, Vol. 17, 3555-3575.

©2021 AIR Worldwide

building codes AIR engineers refine and validate these functions through the use of post-disaster field survey data and through an exhaustive analysis of detailed loss data from actual events.

The AIR vulnerability model includes temporal and regional adjustments that account for changes in building codes and their enforcement, changes in building construction practices and other factors affecting the regional vulnerability over time. The model differentiates between different building design regions in Florida, based on building codes and other design guidelines, and the model's vulnerability functions are modified accordingly. It is assumed, for example, that buildings in the southern, coastal part of the state are characterized by higher degree of wind resistivity than those in more northern and central regions. The model also differentiates buildings built in different time periods throughout Florida. Engineering judgment and published research data went into the initial development of the vulnerability adjustments, and subsequent refinement of these factors has been based upon exposure and loss data provided by clients.

The resulting vulnerability functions reflect the evolution of building codes and the higher level of engineering attention in newer construction relative to older construction. The model captures the state-of-the-art when it comes to adoption and enforcement of building codes in Florida through FBC 2017, which is the latest version governing the design and construction of personal residential and commercial residential buildings. The vulnerability functions have been validated by comparing actual losses with simulated losses for different areas and time periods in Florida and have been found to be reasonable and theoretically sound. Claims data from recent hurricanes in Florida indicate that buildings built prior to 1995 are significantly more vulnerable than buildings built after 1995. Based on the adoption and evolution of building codes, the AIR Hurricane Model for the U.S. includes the following year-built categories for Florida: pre-1995, 1995-2001, 2002-2011, and post-2011. In addition to the building codes themselves, the model accounts for the impacts of structural aging and deterioration and of building technology changes on the vulnerability of buildings. Buildings built prior to 1995 are perceived as old from both these perspectives, and buildings built within the last six years (2015-2020) are considered new from an aging perspective. Between 1995 and 2015, there is a continuous change in the year-built adjustment to account for structural aging and similar factors. For each year-built category, the Individual Risk Model (Appendix D) has been used to estimate the vulnerability within the year-built band.

Separate vulnerability functions have been developed for buildings built to the minimum requirements of the Florida Building Code (FBC 2001 and more recently FBC 2010). While six unique building categories were identified in the entire state of Florida by taking into consideration the design wind speed, the terrain exposure category, and the requirements of the Windborne Debris Region (WBDR) and the High-Velocity Hurricane Zone (HVHZ), as specified in FBC 2001, eleven unique building categories (described in Appendix 9) were identified in the entire state to satisfy the aforementioned considerations of design wind speed, terrain exposure category, WBDR and HVHZ in accordance with FBC 2010. Note that the intermediate versions of FBC from FBC 2001 and FBC 2007 and the associated supplements have no material differences that impact the wind vulnerability. Similarly, subsequent versions that FBC adopted post-2011, including FBC 2010, FBC 2014, and FBC 2017 have no material differences that impact the wind vulnerability of buildings. The vulnerability functions for these building categories were derived using the building features and mitigation measures from the AIR Individual Risk Module that meet the minimum requirements of FBC 2001 and FBC 2010.

©2021 AIR Worldwide

While the design and construction of site-built buildings are based on building codes, the design and construction of manufactured homes has been regulated and governed federally by the U.S. Department of Housing and Urban Development (HUD) since the National Manufactured Housing and Construction Safety Standards Act was passed in 1974. Regulations governing the design, construction, and installation of manufactured homes have evolved considerably since passage of HUD's National Manufactured Housing and Construction Safety Standards Act in 1974. There are two clear dates with respect to manufactured home construction regulations: 1976, when HUD code was first enforced; and, 1994 when the HUD code was reinforced in the wake of Hurricane Andrew (1992). In 1999, regulations for tie-downs were updated for Florida. The zinc plating for tie-down straps was increased to provide better resistance to corrosion. In 2008, HUD added a new standard that required manufactured homes in wind zones II and III to have tie-downs. To account for the spatial and temporal variation in the vulnerability of manufactured homes, the AIR model uses the following year-built categories: pre-1976, 1976-1993, 1994-1998, 1999-2007 and post 2007.

48. ***Besides those identified in the V-2 disclosures (Vulnerability Standard Number 2 of the Florida Commission on Hurricane Loss Projection Methodology), identify and explain all mitigation measures used by the model.***

The AIR Hurricane Model for the U.S. includes the capability to account for the impact of secondary building and environmental characteristics on the vulnerability of individual risks. The modeling methodology was developed using an engineering-based framework system in a structured approach, as described in detail in Attachment D.

Based on structural engineering expertise and building damage observations made following historical hurricanes, more than 25 building features have been identified as having a significant impact on building damage and losses. Options corresponding to each feature are identified based on construction practice. Algorithms for modifying the damage functions are developed based on engineering principles and observational data. The AIR model supports any combination of multiple building features and produces a modification function that is applied to the base vulnerability function. The modification function captures the changes to building vulnerability that result when certain building features are present, and when information on such building features is known. The modification function varies with wind intensity to reflect the relative effectiveness of a building feature when subject to different wind speeds. A list of the secondary characteristics available in the model is provided in Attachment D.

49. ***Describe in detail how the model estimates damage from bypassing storms. Include examples of storms that reach hurricane strength prior to or subsequent to causing damage in Florida and are not of hurricane strength when damage is caused in Florida.***

In the AIR U.S. US Hurricane Model, bypassing storms are defined as those that pass close enough to land to produce damaging winds (≥ 40 mph) onshore, but do not actually make landfall. The AIR model generates bypassing storms through the track generation procedure described in response to question 34 above. The intent of the procedure is to ensure that hurricane losses are included when a National Weather Service watch or warning is in effect and damaging winds are over land. Damage is calculated from the point in time that the storm reaches hurricane strength, through the lifetime of the event while the calculated wind speed is greater than or equal to a threshold of 40 mph. An example of historical bypassing storm in Florida, which is included in the Official Hurricane Set of the Florida Commission, is NoName04-1935.

©2021 AIR Worldwide

50. ***Describe in detail how you handle multiple landfalls in the model and how you handle multiple events at a single location in a single season.***

Because the AIR model follows each simulated hurricane from the time of its inception until its dissipation, hurricanes with multiple landfalls are part of the simulation. Same as the frequency of single-landfalling and bypassing storms, the simulated frequency of multiple landfalls is consistent with the historical frequency of these storms during the period 1900-2018.

51. ***Identify any storms in the historical or the stochastic storm set that cause damage subsequent to 72 hours after the first damage-causing winds in the state of Florida. If your model assumes that this is not possible, explain how one can accurately make such an assumption.***

The model does not constrain the length of time during which damaging winds can be in effect. In AIR's simulated catalog of more than 30,000 Florida events, less than one percent of the storms have duration greater than 72 hours.

52. ***Provide complete detail concerning the modeler's investigation and handling of claim practices of insurance companies when data for those companies is used to develop or verify model calculations.***

AIR accompanies its requests for client company experience data with a supplemental questionnaire relating to company underwriting and claims practices. Any necessary adjustments to be consistent with the model are made to client data based on responses to these questions. If adjustments are applied to the data as indicated by the client, such adjustments are noted in the PIAF.

53. ***Describe the analyses performed to validate the model output loss costs using insurance company data that may or may not include the effects of demand surge. Demonstrate how any analyses where Hurricane Andrew losses are used considers the presence of demand surge.***

No adjustment was made to loss data for Hurricane Andrew to remove implicit demand surge. AIR does not calibrate the model damage functions to losses from any one event. Undue weight was not given to Hurricane Andrew in the validation process.

54. ***Describe the methods used to account for the implementation of multiple deductibles in the insurers' claim payment historical records for policy periods where more than one hurricane caused damage at a single location. Describe how multiple deductible claim experience in the historical record is included in the projection of future loss costs. Describe any recent changes in the process used to account for multiple deductibles.***

AIR has implemented the Florida seasonal deductibles in the software. The AIR model explicitly enables assessment of the probability and costs of multiple-event seasons. It does so by including annual frequency of occurrence among the primary variables in the stochastic catalog, which is a key model parameter. Each simulated year may have zero, one or multiple events. This approach for generating the event catalog makes it straightforward to determine the probability and losses of multiple-event seasons.

©2021 AIR Worldwide

Historical loss data from multiple events causing damage at the same location was not used in the development or validation of the model.

55. ***Provide documentation of the rules and procedures that assure accuracy of insurance data used in developing or validating the model.***

AIR accompanies its requests for insurance data used for model development or validation with a supplementary questionnaire relating to company underwriting and claims practices. Any necessary adjustments to be consistent with the model are made to client data based on responses to these questions. If adjustments are applied to the data as indicated by the client, such adjustments are noted in the PIAF.

56. ***Justify any changes from the immediate earlier version of your model of greater than five percent in weighted average loss costs for any county.***

As mentioned previously, the AIR Hurricane Model for the U.S. Version 1.0.0 has been reviewed and found acceptable for use in rate filing in Florida by the FCHLPM in June 2021, respectively. As part of the review process, AIR justified any percentage changes in weighted average loss costs for any county that are greater than 5% to the Professional Team (Pro-team) and the Commission. The FCHLPM has found AIR's explanation reasonable considering the updates to the model. In general, the most recent updates to the U.S. US Hurricane Model focus on the event generation component, (which includes updates to the historical and stochastic catalogs), building vulnerability, the ZIP Code database and the industry exposure database (affecting the average physical properties). A summary description of changes that affect the personal or commercial residential loss costs or probable maximum loss levels is provided below. The overall change in the average zero deductible statewide residential loss cost that has been reviewed by the Florida Commission is an increase of 0.3%.

Event Generation Component (i.e. Catalog): For this model release, AIR's historical storm set has been updated, incorporating track information from the 2019 version of HURDAT2. These updates have resulted in a 0.3% decrease in losses.

Building Vulnerability Updates: Overall, the vulnerability related updates resulted in a 0.1% increase in losses. The changes in the vulnerability component of the model since the previously accepted model include:

a) The pre-computed factors which adjust the base wind structural vulnerability accordingly when the user provides no year built information, as opposed to a known year built, have been updated to be relevant through 2020. This includes adjusting the underlying year built weighting assumptions to utilize the latest census and tax assessor data regarding building stock age. This is a technical data update.
b) Vulnerability adjustments that account for structural aging and building technology changes, along with aging and deterioration of roofs have been updated to be relevant through 2020. This is a technical data update.
c) The implementation of the "roof year built" secondary risk feature has been enhanced to default to a new roof for those structures that are built within the last ten years.
d) The logic of roof age assignment has been updated to assign buildings built within the last 10-20 years to have an "average" roof year built when the roof year built is unknown.

©2021 AIR Worldwide

Geographical or Other Updates: The updates in geographic and other data have resulted in a 0.5% increase in losses. The updates include:

a) The ZIP Code and Industry Exposure databases are updated each year. ZIP codes have been updated to April 2020. AIR's Industry Exposure Database for the U.S. has been updated as of 12/31/2019. The Industry Exposure Database update affects estimated industry losses and resulting demand surge factors. This is a technical update.
b) The U.S. Census Topological Integrated Geographic Encoding and Referencing (TIGER)/Line data, which supports street level geocoding, was updated to be relevant through 2019.

57. ***Provide sensitivity analyses on annual frequency, central pressure, Rmax, forward speed, and mean damage. Explicitly state the statistical techniques used to perform these analyses. Provide displays of these analyses in a graphical format (e.g. contour plots with temporal animation).***

AIR has done extensive sensitivity testing on all aspects of the US Hurricane Model. The sensitivity analyses performed include one-parameter-at-a-time studies as well as multi-parameter studies where several input variables are varied simultaneously. In most of these studies, the output variable of interest has been the insured losses evaluated at the state, county, and ZIP Code level. However, the changes in wind speed resulting from changes in the input variables have also been studied. The approaches used include changing the probability distributions used for key input variables and changing the parameters associated with these probability distributions. Model output from base-case simulations has also been examined to identify sensitive input variables.

AIR uses a Weibull distribution to model central pressure. However, the impact on the losses of using a Lognormal distribution has also been tested. For radius of maximum winds, the Lognormal has been considered as an alternative to the Normal distribution for the noise term in the regression model for Rmax. The impact of varying the bounds placed on the radius of maximum wind for very intense storms has also been evaluated. On the vulnerability side, the sensitivity studies performed include changing the damage functions used in the loss estimation.

AIR uses a Negative Binomial distribution to model annual landfall frequency with the parameters estimated using historical data since 1900. Due to the limited historical record, sampling error is present in the parameter estimates. AIR has examined the impact of the sampling error by perturbing the mean of the annual landfall distribution and examining the impact on losses.

In a multi-parameter study focusing on sampling error, AIR included three input variables: annual landfall frequency, central pressure, and radius of maximum wind. The level of damage was included as a fourth factor in the study. The study utilized a 2^4 factorial design (see, for example, Box, Hunter, and Hunter, 1978[6]) in which the mean levels of each of the four variables were perturbed and placed at two new settings, high or low, resulting in 16 experimental combinations. The high and low mean values for each input variable were generated by changing the mean values of the probability distributions for these variables by one standard error, either up or down. Main effects and interaction effects were computed using ZIP Code level loss costs in Florida as output variable. Among the input variables included in this study, changing central pressure was identified as having the largest impact on losses.

©2021 AIR Worldwide

As part of its 2009 Florida Commission submission, AIR assessed the sensitivity of temporal and spatial model wind speeds with respect to the simultaneous variation of six input parameters: central pressure (CP), radius of maximum winds (Rmax), forward speed (VT), far field pressure (FFP), gradient wind reduction factor (GWRF), and peak weighting factor (PWF). Details of the sensitivity analysis performed can be found on the FCHLPM website (AIR 2009 Form S-6 Analysis). Please note that the Commission determined that a new sensitivity analysis was not needed for the updated model during the 2019 submission cycle.

58. ***Provide detailed control and flow diagrams, completely and sufficiently labeled for each component as well as interface specifications for all components in the model. Each diagram must include components, sub-components, arcs, and labels.***

AIR maintains a primary document collection including a component design document, which contains detailed control and data flow diagrams and interface specifications that illustrate the component design of the Touchstone® software system and the architecture of the AIR Hurricane Model for the U.S., its components and sub-components. The component design document includes detailed control and data flow diagrams for event generation, and class diagrams for all other portions of the US Hurricane Model and Touchstone® system.

59. ***Provide detailed unit test documentation for testing on each model component, including all aspects of the model (meteorology, actuarial, vulnerability, statistics, user interface, and other components).***

All members of AIR's software development group are responsible for ensuring the quality of their work through unit testing. Unit tests are performed for individual software components, independent of all other components, and are documented.

Testing Teams

Formal testing of Touchstone and the U.S. US Hurricane Model is the responsibility of the Software QA, Model QA and Core QA groups. Figure 22 below illustrates at a high level the testing interaction within the development process.

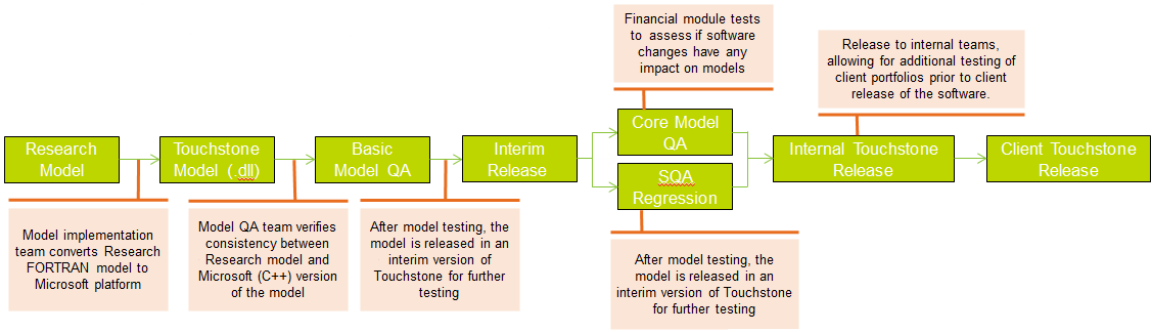

Figure 22. QA Team during the Development Process

The responsibility of each testing team is as follows:

©2021 AIR Worldwide

- Software QA—Responsible for testing the implementation and functionality of Touchstone. This group is engaged with the entire software development process, including the review of requirements and design documents.
- Model QA—Responsible for the testing of the U.S. US Hurricane Model. During the Model QA testing process, the Model QA team compares the loss results from the FORTRAN model against those from Touchstone and determines if the loss results agree from both platforms. In addition, they also verify the consistency of data between software builds. Any discrepancies are investigated. Client consulting team generates the output range reports and probable maximum loss results and compares them against the results from the previous release version. The group has weekly meetings to review ClearQuest tickets and work progress. To ensure the consistency of the results, the Model QA team develops and executes test cases and use Excel and SQL Server during the verification process. All test plans and test results are peer review primarily by the Research group. Bugs found in the QA process are resolved by the Model Development and Research groups.

Core QA—Responsible for model validation, including:

  - Building summary statistical tables on the physical event parameters from the 50K Standard and Full Historical Catalog and compares them to summary stats tables prepared by Research and Modeling team. The purpose of this test is to validate the physical peril change expectations. The test cases and results are peer reviewed and approved.
  - Prepares industry loss change management data set of exhibits for Florida, including 1) full model domain and 2) detailed-level. These exhibits include analysis permutations of event catalogs, analysis options and peril options, as well as comparison of state, county and ZIP Code of summary EP curves. The final analytics are summarized into an internal document, which is distributed among and reviewed by stakeholders.

Core QA test plans and test results are reviewed by various stakeholders, including Product Management, Software Development, Research, Core QA and Software QA.

Test Plan Development

The following steps outline the process for developing test plans.

Table 12. Test Plan Development Process

Step	Description
Gathering Requirements	Understand the objective and details of the assignment. This is accomplished by gathering the requirements from requirement documents, product management, and the appropriate subject matter experts.
Create Test Plan	Plan the testing to be performed. The plan includes the goal of the testing, what testing is required for the project/issue, as well as the regression and test types that will be employed.

©2021 AIR Worldwide

Step	Description
Review Test plan	Cross-functional review and acceptance of the plan; changes are incorporated as appropriate. Test plans are reviewed by various stakeholders, including Product Management, Software Development, Research, and Technical Services, and Client Consulting.
Generate Test Cases/Scripts	Document the steps required for testing. Include enough detail to make the test repeatable and document the expected results. Create test automation (scripts) as appropriate.
Execute Tests	Execute tests.
Review Results and Manage Issues	Review the test results and, when applicable, enter all issues into the tracking system and verify completed issues. Test results are reviewed by various stakeholders, including Product Management, Software Development, Research, Technical Services, and Client Consulting,
Report Results	Document the test results. Detail all the activities performed, archive data with the results, and announce completion.

Test Types

The types of tests conducted at AIR include the following. In addition, to evaluate the testing progress for each build of the software, the QA team maintains an overall SQA Status spreadsheet that enables them to evaluate the status of test plans in real-time:

Unit Testing: Unit testing focuses on the critical functions that are involved with calculating hurricane loss distributions. QA analyzes these functions for their proper minimum and maximum input values. The software code makes these functions accessible to the unit-testing program and, when the unit-testing flag is turned on, the functions log the output data. When running the unit-test program, the testing engineer may specify the following types of test inputs for each function:

- Custom—The engineer specifies a specific input data set for testing the function.
- Random—The unit-test program generates a random data set for testing the function. As part of the data generation, the program generates out-of-bound data to determine if the function handles erroneous inputs correctly.
- Linear—The unit-test program generates a data set by varying each input parameter by a fixed increment within the range of [90% of the minimum, 110% of the maximum] and records all possible combination of input parameter values. The test result is intended for trend analysis and boundary checking analysis.

For each test, the input and output data for each function is recorded in a file and the test data is analyzed for proper behavior.

Integration Testing: The mechanisms for unit testing are easily adopted for integration testing. After verifying that functions at a certain level behave correctly, QA verifies the correctness of other functions that invoke only the validated functions.

Aggregate Testing: To ensure broad coverage in software testing, for example, tests may include:

©2021 AIR Worldwide

- Average loss for a house of certain construction type and value for all ZIP Codes in the United States.
- Losses for a group of selected locations, building construction types, and four occupancy classes are computed and compared. Effects of deductibles are also computed and compared.

For certain aggregate tests, tests use both the new and previously released versions of the software. For each test, the results are compared between two software versions. If a discrepancy is detected between the two results, the testing group refers the case to the appropriate stakeholder, such as Research or Software Development, for further analysis.

User Interface Testing: AIR ensures that implementation of each version-specific update functions as expected on the Touchstone User Interface.

Performance Tests: AIR evaluates performance between the new and previously released version of the software. Any unexpected performance issues are investigated further.

Test Tools

Tools used during the testing process include:

- SilkTest: Build and execute automated test cases.
- IBM Rational Performance Tester: Execute UI Load Testing Performance Tests
- Beyond Compare: Compare output and validate test results.
- ClearQuest: Bug tracking and management.
- Microsoft Excel: Perform basic calculations of model losses and model parameters, such as comparisons between model versions, loss ratios, and loss cost ratios.

60. ***Provide the client data processing procedure requirements that assure the integrity and consistency of data.***

AIR maintains a client data processing procedures document in order to provide a structured approach to the analysis of client data. The document covers data log-in, mapping of client data to AIR codes, importing the data into the software, and data queries that are geared towards uncovering issues of data quality or completeness and ensuring that unique conditions or special reporting features are properly considered.

About AIR Worldwide Corporation

AIR Worldwide (AIR) provides risk modeling solutions that make individuals, businesses, and society more resilient to extreme events. In 1987, AIR Worldwide founded the catastrophe modeling industry and today models the risk from natural catastrophes, terrorism, pandemics, casualty catastrophes, and cyber incidents, globally. Insurance, reinsurance, financial, corporate, and government clients rely on AIR's advanced science, software, and consulting services for catastrophe risk management, insurance-linked securities, site-specific engineering analyses, and agricultural risk management. AIR Worldwide, a Verisk (Nasdaq:VRSK) business, is headquartered in Boston with additional offices in North America, Europe, and Asia. For more information, please visit www.air-worldwide.com.

AIR Worldwide List of Staff

Professional Credentials

In total, the AIR technical staff consists of more than 500 professionals, more than 80 of whom hold PhD credentials in their fields of expertise. While many of these professionals have been directly or indirectly involved with the U.S. Hurricane Model, we list below only those individuals who have contributed significantly to model development, enhancement, testing and/or validation.

Credentials are summarized in table below. Note that all of the individuals named are full-time employees of AIR.

2.A.1. Meteorology: Name, Education	Years at AIR	Relevant Experience
Boyko Dodov Ph.D., Hydrology, University of Minnesota	15	Dr. Boyko Dodov is a Vice President and Director of Atmospheric and Flood Modeling in AIR's Research and Modeling group. He received his B.S. in Hydrogeology from the Higher Institute of Mining and Geology in Sofia, Bulgaria, and his Ph.D. in Civil Engineering - Hydrology from the University of Minnesota. Boyko is the author of numerous peer-reviewed papers and presentations related to the implementations of mathematical and statistical approaches to stochastic simulation of weather and climate phenomena.
Phillip Jue B.S., Atmospheric Sciences, University of Illinois, Champaign	6	Mr. Jue is a scientist, joined AIR in 2014 first as an intern and in 2015 as a full-time employee. Phil has a bachelor in Atmospheric sciences from the University of Illinois Champaign. Mr Jue has been working on calibration of historical events on select models here at AIR. Most recently he has been leading the real-time effort during hurricane seasons.
Sylvie Lorsolo Ph.D., Geosciences (Atmospheric Sciences), Texas Tech University	8	Dr. Lorsolo, a Senior Scientist, joined AIR in 2012 as an Atmospheric Scientist in the Research Department. Most recently, Dr. Lorsolo worked as an Assistant Scientist for the NOAA/Hurricane Research Division at the University of Miami where she focused on observational studies of the hurricane boundary layer and developed expertise on collecting and analyzing airborne data for a better understanding of hurricane intensity change. Prior to that, Dr. Lorsolo was a Research Assistant at Texas Tech University, where she studied hurricane structure at landfall and was responsible for field experiment design for land falling tropical cyclones. She also conducted damage surveys after hurricane landfall and tornado events. In addition, Dr. Lorsolo earned her Ph.D. in Geosciences from Texas Tech University.
Jeff Strong Ph.D., Atmospheric & Oceanic Sciences, Princeton University	1	Dr. Strong joined AIR in 2019 as a Scientist in the Research Department working on tropical cyclone hazard modeling. Dr. Strong came to AIR from the Lamont-Doherty Earth Observatory of Columbia University where, as a postdoctoral research scientist, he collaborated with the NASA Goddard Institute of Space Studies to develop the next-generation of global tropical cyclone models. Prior to that work, Dr. Strong was employed as a postdoctoral research scientist at the Scripps Institution of Oceanography at UCSD studying the simulated impacts of aerosols on global tropical cyclone development. Dr. Strong earned his Ph.D. and M.A. from Princeton University and a dual B.S. in Environmental Science and Mathematics from the University of Virginia.
Eric Uhlhorn Ph.D., Meteorology and Physical Oceanography, University of Miami	5	Dr. Uhlhorn joined AIR in 2015 as a Principal Scientist in the Research Department. He most recently worked as a Meteorologist for NOAA/Hurricane Research Division, where he used in situ and remote sensing observational data from aircraft to gain better understanding of tropical cyclone surface wind field structure. Prior to that, he worked as a Senior Research Associate III for the Cooperative Institute for Marine and Atmospheric Studies for the University of Miami. Dr. Uhlhorn earned his Bachelor of Science Degree in Meteorology from Florida State University, his Master of Science Degree in Physical Oceanography from Florida Institute of Technology, and his Ph.D. in Meteorology and Physical Oceanography from the University of Miami.
Richard Yablonsky Ph.D., Oceanography (Physical), University of Rhode Island	6	Dr. Yablonsky joined AIR in 2014 and is currently a Senior Scientist in the Research Department, where he leads the Storm Surge Team. Since joining AIR, he has been directly or indirectly involved in a variety of projects, including tsunami hazard modeling and all aspects of tropical cyclone hazard modeling (storm surge, precipitation, frequency, track, and intensity). Previously, Dr. Yablonsky worked as a Marine Research Scientist (2013-2014) and a Marine Research Associate (2009-2013) at the University of Rhode Island's Graduate School of Oceanography in Narragansett, RI, specializing in modeling air-sea interaction in tropical cyclones.

2.A.1. Meteorology: Name, Education	Years at AIR	Relevant Experience
		He has also held a Visiting Scientist Appointment at the Developmental Testbed Center in Boulder, CO (2014). Dr. Yablonsky obtained a Ph.D. in Oceanography from the University of Rhode Island (2009) and three degrees from North Carolina State University: M.S. in Atmospheric Science (2004), B.S. in Meteorology (2002), and B.A. in Chemistry (2002).
Ying Zhou Ph.D., Environmental Science, SUNY College of Environmental Science and Forestry	1	Dr. Zhou joined AIR as a Scientist in the Research Department. Previously, Dr. Zhou was a Consultant for FM Global, where she worked on the tracking and detection of extratropical cyclones. Prior to that, Dr. Zhou was a Research Assistant at SUNY College of Environmental Science and Forestry, where she studied the impact of extratropical cyclones, wildfires, anthropogenic and natural emissions on tropospheric ozone. In addition, she maintained atmospheric instruments to monitor air quality. Dr. Zhou earned her Ph.D. in Environmental Science from SUNY College of Environmental Science and Forestry.

2.A.2. Statistics: Name, Education	Years at AIR	Relevant Experience
Suilou Huang Ph.D., Oceanography, University of Rhode Island	8	Dr. Huang is a Senior Scientist II in the Research Department, Statistics and Applied Mathematics group, at AIR. Since she joined AIR in 2013, she has been using her statistics expertise, data analysis, and computer programming skills in a variety of projects such as developing the Canada Tropical Cyclone catalog, and the U.S. and Australia Wildfire models; updating the U.S. Hurricane catalog, providing support to the AIR Hurricane Model for the U.S. submissions to the Louisiana State Hurricane Commission and FLHCM; and providing client support. She also gives statistical training courses to AIR employees. Prior to joining AIR, Dr. Huang worked as an associate technical staff member at MIT Lincoln Laboratory, a guest scientist at Woods Hole Oceanographic Institution, and a research scientist/adjunct faculty member at New Mexico Institute of Mining and Technology. Dr. Huang holds a B.A. in Chemistry from Sun Yat-Sen University, China, an M.S. in Statistics from the University of Rhode Island, and a Ph.D. in Oceanography from the University of Rhode Island.
Susan Tolwinski-Ward Ph.D., Applied Mathematics, University of Arizona	7	Dr. Tolwinski-Ward is a Principal Scientist at AIR, with a background in data-model fusion and uncertainty quantification. She has been modeling the statistical climatology of tropical cyclones at AIR since 2013. She holds a Ph.D. in Applied Mathematics from the University of Arizona with a minor concentration in Atmospheric Sciences. Prior to beginning work at AIR, she was a National Science Foundation Mathematical Sciences Postdoctoral Research Fellow at the Institute for Mathematics Applied to Geosciences at the National Center for Atmospheric Research.

While many outside experts have been consulted on various aspects of the vulnerability functions, the primary full-time employees currently involved in model development are:

2.A.3. Vulnerability: Name, Education	Years at AIR	Relevant Experience
Sarah Bobby Ph. D., Civil and Environmental Engineering and Earth Sciences, University of Notre Dame	5	Dr. Bobby joined AIR in 2015 as an Engineer 1 and Manager in our Research Department. Prior to working with AIR, Dr. Bobby worked as a Graduate Research Assistant for the University of Notre Dame, where she created an in-house probabilistic risk assessment program for the fragility/damage analysis of structures under wind and seismic hazards through the integration of hazard and structural models. Dr. Bobby earned her B.S in Civil Engineering as well as her Ph.D. in Civil and Environmental Engineering and Earth Sciences from the University of Notre Dame.
Jayanta Guin Ph.D., Civil Engineering, State University of New York, Buffalo	23	Dr. Guin is Executive Vice President and Chief Research Officer responsible for operational and strategic management of the AIR Research and Modeling team. Under his leadership, the team has expanded the global coverage of natural catastrophe models and continues to enhance existing models. He has more than ten years of experience in probabilistic risk analysis for natural catastrophes worldwide. Dr. Guin has led the research effort on a number of capital markets transactions that involved transfer of risk due to earthquakes, cyclones and windstorms. Prior to his graduate studies, he worked as a structural engineer with a leading design consultant in India. Dr. Guin received his B.S. in Civil Engineering from Jadavpur University in India. He earned his M.S. and Ph.D. in Civil Engineering from the State University of New York, Buffalo, with a specialization in dynamic soil-structure interaction and computational mechanics. As a member of the Computational Mechanics Laboratory at SUNY, Buffalo, Dr. Guin gained extensive experience in finite-element and boundary-element analyses for a wide range of engineering problems.
Tim Johnson Ph. D., Civil Engineering, Florida Institute of Technology	5	Dr. Johnson joined AIR in 2015 as an Engineer in AIR's Research Department. Prior to working with AIR, Dr. Johnson worked as a Vulnerability Modeler/Graduate Research Assistant for the Florida Public Hurricane Loss Model where he worked as the lead engineer in the vulnerability model team of the FPHLM. Dr. Johnson earned his Bachelors, Masters and Ph.D. in Civil Engineering from Florida Institute of Technology.
Cagdas Kafali Ph.D., Civil and Environmental Engineering, Cornell University	13	Dr. Cagdas Kafali is a Senior Vice President in AIR's Research and Modeling group, working primarily on wind vulnerability of civil engineering systems. He has been involved in the development of many of AIR's wind models, particularly the Asia-Pacific typhoon models and the European Extratropical Cyclone model, and more recently the U.S. and Canada wind storm models. Dr. Kafali holds an M.S. in Structural Engineering from Case Western Reserve University and a Ph.D. in Civil Engineering from Cornell University with a minor in Applied Mathematics. In his dissertation, he developed a probabilistic methodology for assessing performance of structural/nonstructural systems in a multi-hazard environment.
Karthik Ramanathan Ph.D., Civil and Environmental Engineering, Georgia Institute of Technology	8	Dr. Ramanathan is an Assistant Vice-President and Principal Engineer in AIR's Research and Modeling Department, working primarily on the wind and flood vulnerability of civil engineering systems. Dr. Ramanathan joined AIR in 2012 as an Engineer in our Research and Modeling Department. Prior to AIR, he worked as a Graduate Research Assistant with the School of Civil and Environmental Engineering at Georgia Institute of Technology, where he earned both his Ph.D. and M.S. in Civil and Environmental Engineering with a special focus in Earthquake Engineering and Structural Reliability. Prior to joining

2.A.3. Vulnerability: Name, Education	Years at AIR	Relevant Experience
		Georgia Tech, Dr. Ramanathan obtained an M.S. from the University of Pittsburgh in Civil and Environmental Engineering with a special emphasis in Structural Engineering and Mechanics.
Kun Yang Ph.D., Civil and Environmental Engineering, University of Delaware	2	Dr. Yang joined AIR in 2018 and is an Engineer II in our Research Department. Prior to working with AIR, Dr. Yang worked as a Graduate Research Assistant for the University of Delaware, where he worked on an inter-disciplinary hurricane evacuation project that integrates meteorological and hydrological models, sociology prediction model, and transportation engineering model to support evacuation order decision making. Dr. Yang earned his B.E. in Automation with a focus on systems engineering from Huazhong University of Science and Technology, and his Ph.D. in Civil Engineering from the University of Delaware.

2.A.4. Actuarial Science: Name, Education	Years at AIR	Relevant Experience
Nicholas Brewer B.A., Actuarial Science, Bryant University	2	Mr. Brewer joined AIR in 2018 in the Consulting and Client Services Group as a Risk Analyst. He works on the Regulatory and Rating Agency team and primarily works on regulatory projects with departments of insurance. Previously he worked for Mercer as a Client Services Pensions Analyst. Before that, he worked for Allied World as an Actuarial Assistant. Mr. Brewer earned a B.A. in Actuarial Science from Bryant University.
Brendan Flaherty B.A., Mathematics, Stonehill College	2	Mr. Flaherty is a Manager in AIR's Consulting and Client Services Group. He works in the Regulatory and Rating Agency market segment assisting with various regulatory engagements and serving as primary liaison with the rating agencies. Previously, Mr. Flaherty worked for Mercer, as an actuarial consultant, specializing in long term financial forecasting and risk management strategies for U.S. pension plans. Mr. Flaherty earned a B.A. in mathematics from Stonehill College.
Stacey Gotham B.A., Mathematics, Rutgers College	12	Ms. Gotham is a Senior Actuary in the Consulting Services Group at AIR. She is a member of the American Academy of Actuaries AAA and a Fellow of the Casualty Actuarial Society FCAS. Also, she is also a member of the AAA's Property and Casualty Extreme Events and Property Lines Committee, and the Natural Catastrophe Subcommittee. Prior to joining AIR, Ms. Gotham was an actuary for the state of Massachusetts and held various actuarial positions with Liberty Mutual Insurance Group. She has a B.A. in Mathematics from Rutgers College.
Christy Shang M.S., Mathematics, University of Connecticut	9	Ms. Shang is a Manager in the Consulting and Client Services group at AIR. She works in the Regulatory and Rating Agency market segment, where she ensures compliance with all regulatory requirements of catastrophe models and assists clients in dealing with regulators and rating agencies. Ms. Shang holds a B.A. in Economics from Boston University and an M.S. in Mathematics from the University of Connecticut.

2.A.5. Computer/ Information Science: Name, Education	Years at AIR	Relevant Experience
Donald Alcombright B.S., Information Systems, Daniel Webster College	13	Mr. Alcombright is the Software Support Manager in AIR's Technical Services Group.

2.A.5. Computer/ Information Science: Name, Education	Years at AIR	Relevant Experience
Sikondrulu Alekhya B.E in Electronics and Communication, Vasavi college, Hyderabad, India	1	Ms. Alekhya took her first career step at AIR in June 2019 as Software Quality Assurance Engineer. She has received her bachelors degree in Electronics and Communication Engineering from Vasavi college of Engineering, Hyderabad. Her academic projects include Developing a Mobile Application called “College Diaries” for notifying students with the current happening in the college, Medication Reminder box and Mail Notification system using Bluetooth.
Vijay Santosh Alla M.S. Computer Science, New Horizon College of Engineering (Formerly National Institute of Management and Information Sciences, Bangalore University), India	1	Mr. Vijay Santosh is a Senior Manager in AIR’s Quality Assurance Team and joined AIR in Jan 2020. He worked with Publicis Sapient for 9+ Years before joining AIR in Jan 2020. He has overall 16+ years of working experience with Products and Services clients. He and his team are responsible for on time delivery of Product and ensuring the delivery quality meets the set standards. He holds a master’s degree in Computer Science and bachelor’s degree in Statistics. He has good understanding of Data Science Architecture and currently pursuing a course for Data Science Architect.
Tejaswi Battula M.S., Computer Science Kansas State University	5	Ms.Tejaswi joined AIR in June 2015 as a Database Engineer in the Software Development Group and is now a Senior Database Engineer. She has completed a Bachelor of Technology in Computer Science from JNTU, India. Prior to joining AIR she worked as a Database Engineer at Merkle,Inc.
Abhinav Chintakindi B.E., Computer Science and Engineering, Vasavi College of Engineering(OU), Hyderabad, India	7	Mr. Abhinav Kumar took his first career step at AIR in July 2013 as Software Developer I into MIG team. Currently he is taking responsibilities as "Senior Software Engineer II" in the Model Implementation Group at AIR Hyderabad, working on implementing the Hurricane Model for the United States, as well as other AIR models, in Touchstone. He completed his Bachelors of Engineering degree in Computer Science and Engineering from Vasavi College of Engineering (OU), Hyderabad.
Dennis Costello B.S., Civil and Environmental Engineering, Cornell University	15	Mr. Costello joined AIR in 2005 and is a Senior Product Manager responsible for model implementation within the AIR's software products.
Igor Cizelj Ph.D., Mechanical Engineering, Boston University	6	Dr. Igor Cizelj is a Team Lead in the Core Quality Assurance Team. He joined AIR in 2014 as a Core Quality Assurance Associate in the Product Management group. At AIR, he has created tools and crafted workflows that allow efficient, traceable, and repeatable validation of catastrophe models in all phases of model development, implementation, and quality assurance. He has have worked on earthquake, tsunami, wildfire, flood, and wind catastrophe models. Before joining AIR, during his research years at Boston University, Dr. Cizelj has proposed and evaluated methods and algorithms for synthesizing control strategies for different robotic models from temporal logic specifications. Dr. Cizelj holds a Ph.D. in Systems Engineering from Boston University and an M.A. in Mechanical Engineering from University of Zagreb.

2.A.5. Computer/ Information Science: Name, Education	Years at AIR	Relevant Experience
Rohan Das MSc. Actuarial Science, ASIBAS – Amity University	4	Mr. Das is a Model QA Analyst II in AIR's Model Quality team. AIR has been the first step for Mr. Das in his career. His current responsibilities include the validation of models implemented by MIG on Touchstone against the Research model and also independent validation of the model from Touchstone to ensure that the behavior of the model is on expected lines. Models validated in the past include U.S. Tropical Cyclone's Builder's Risk Module, Japan Tropical Cyclone, Japan Inland Flood, Europe Tropical Cyclone, Europe Severe thunderstorm, U.S. Inland Flood-TS8 update, U.S. Tropical Cyclone-TS8 and TS 2020.
Suryanarayana Datla M.E., Structural Dynamics, IIT, Roorkee, India	19	Mr. Datla joined AIR Hyderabad in February 2001 and is currently Vice President of Research and Director for the Model group in Hyderabad. Mr. Datla has more than 18 years of experience in developing catastrophe loss estimation models. His current responsibilities include implementation of catastrophic risk assessment models developed for various regions and perils worldwide into AIR products. He is also involved in development of catastrophe models for various regions/perils and manages the GIS and Flood Research teams in Hyderabad. Mr. Datla holds a M.E. (Masters in Engineering) in Structural Dynamics from IIT Roorkee, India. Prior to joining AIR, he was a senior engineer at RMS India Office at Delhi for three years, where he played a crucial role in the development of earthquake, tornado, and hurricane models. In addition, he conducted post-disaster surveys for Gujarat (1998) and Orissa (1999) cyclones.
Burcu Davidson M.S., Computer Science, Suffolk University, Boston.	21	Ms. Davidson is the Vice President of Software Development at AIR. She joined AIR in 1999. Previously, she worked as an engineer at Turkish Telecom in Ordu, Turkey.
Abhilash Dhadwai Bachelor of Technology, Electronics and Communication Engineering, SRM University, Chennai, India	0.5	Mr. Abhilash Joined AIR in 2020 as Senior Software Engineer I in the Software Development group. Before joining AIR, he has four years of experience in software development using C, C++ at L and T technology services as a Senior Engineer. He has completed his Bachelor of Technology in Electronics and communication from SRM university, Chennai.
Phaninath Dheram M.Phil, Computer Science Jawaharlal Nehru University, New Delhi	8	Mr. Dheram joined AIR in 2012 as Manager and is currently the Senior Manager of the Model Implementation Group in Hyderabad. For three years prior to coming to AIR, Mr. Dheram was an independent software development consultant. For nearly 11 years before that he worked for Mentor Graphics India Pvt Ltd. in Hyderabad, developing software tools for electronic circuits design.
Srimanta Ghosh Ph.D., Hydraulics and Water Resources Eng., I.I.T. Madras, Chennai, India	3	Dr. Ghosh works as Lead Engineer in the Model Quality team at AIR. He is responsible for validating the atmospheric catastrophe risk models. Prior to joining at AIR, he worked as a research scholar and earned Ph.D. in Hydraulics and Water Resources Engineering from Indian Institute of Technology Madras. His Ph.D. dissertation was on Frequency Estimation of Floods, Droughts, and Precipitation at Regional- and Local-scale, using state-of-the-art Statistical, Physical, and Geo-Spatial Models. He has published research articles in reputed peer-reviewed international journals and presented in conferences.

2.A.5. Computer/ Information Science: Name, Education	Years at AIR	Relevant Experience
Rohit Jain B.E. Computer Science, Medicaps Institute of Technology & Management, India	2	Mr. Jain is a Principal Database Engineer in Software Development Group. Prior to joining AIR, he has worked for Eze Software Group in the agile development environment on their financial trading platform. Prior to that he was working with Humana implementing business development solutions for provider team. He has Bachelor of Engineering degree from MITM, India.
Sai Teja Jenula Bachelor of Technology, Civil Engineering, CMRCET, JNT University, Hyderabad	2	Mr. Jenula took his first career step at AIR in May 2018 and is a Model QA Analyst II in the Model Quality Team. His work at AIR is dedicated towards validating the Atmospheric Peril Models and has contributed majorly on testing the US Hurricane, US Inland Flood models and in creating the MQA's Acceptance plans for build certification. Mr. Jenula has achieved the designation of Certified Extreme Event Modeler by completing the requirements of the AIR Institute Certified Extreme Event Modeler Program. He received his bachelor's degree in Civil Engineering from JNT Univerisity, Hyderabad, India.
Aditya Jinna MS., Computer Engineering, Wayne State University, Detroit, MI	20	Mr. Jinna is a Team Lead in AIR's Software Development team. He joined AIR in 2000 and worked extensively across various products at AIR. He has a bachelor's degree in Electronics and Instrumentation Engineering from Osmania University and master's degree in Computer Engineering from Wayne State University in Detroit, MI.
Mohan Kandulapati B.S., Technology & Computer Science, Jawahar Lal Nehru Technological University, India	4	Mr. Kandulapati is a member of AIR's Software Quality Assurance group and holds the title of SQA Engineer II. Mr. Kandulapati previously worked for Tech Mahindra Ltd for three years before joining AIR in 2016. He has a Bachelor's degree in Technology and Computer Science from Jawahar Lal Nehru Technological University in Hyderabad, India.
Karl Kieninger B.A., Economics, University of Virginia	6	Mr. Kieninger joined AIR in 2015 and is a Principal Database Engineer and Team Leadin our Software Development Department. Prior to working with AIR, Karl worked as a Senior Developer for eHana LLC where he participated in agile development of web-based electronic health record system. He also worked as a Senior SQL Developer for Alere Accountable Care Solutions where he developed TSQL and PL/SQL routines for HIPAA compliant HIX platform. Mr. Kieninger has earned his Bachelor of Arts degree from the University of Virginia.
Visweswara Kokkonda Bachelor of Technology, Electronics and Communication Engineering, JNTU, India.	9	Mr. Kokkonda joined AIR, Hyderabad office in July 2011 as a Database Engineer in the Software group and is now a Lead Engineer. He has completed a Bachelor of Technology in Electronics and Communication Engineering from JNTU. Also, Mr. Kokkonda completed an Executive MBA in Project Management and Leadership Management from National Institute of Business Management, Chennai. Prior to joining AIR, he worked at Primaccess Technologies Ltd as a Software Programmer for 4 years, developing Web Applications using ASP.Net, C#, Vb.Net, Ajax, Webservices, JavaScript, MSSQL Server, MySQL, and PostgreSQL. He is a Microsoft-certified SQL Server Developer, Microsoft-Certified C# Developer and Certified Professional Scrum Master.

2.A.5. Computer/ Information Science: Name, Education	Years at AIR	Relevant Experience
Siddhartha Kumar Arya Master of Technology (MTech), Computer Science & Management, Deakin University, Melbourne, Australia	0.5	Siddhartha Kumar Arya joins AIR as an Information Security Manager in our Information Security group. Previously, Mr. Arya worked for Verizon Wireless as a Senior Principal Security Architect. At Verizon he was responsible for Cybersecurity Innovations; data protection; Information Security Management System; Security Operations; Security Architecture & Engineering; Application Security, IAM, Security assessment & testing, and Security Risk management frameworks. Mr. Arya holds Many data security patents for an end to end data protection. He served as Chairperson for multi-organization executive leaders to layout future security product roadmap for Teradata, Hadoop, Oracle, cloud, and open-source related security products. He is also a Chartered Professional Engineer registered with Institution of Engineers Australia. Siddhartha earned an MEng (Systems Engineering and Information Technology) from Birla Institute of Technology and Science (BITS) Pilani, MBA (concentration in MIS) from BITS Pilani and MTech (Computer Science and Management) from Deakin University, Melbourne.
Peter Lewis B.S., Business Administration, Northeastern University	21	Mr. Lewis is a Senior Vice President in the Information Technologies and Services group. He is responsible for developing and executing information technology initiatives in support of AIR's business operations. He also leads the Technical Support and Integration Solution teams, which are responsible for the maintenance and support of AIR's hosted and desktop applications in addition to custom integration with customer's systems. Peter is a Microsoft® Certified Professional specializing in systems support and database administration.
John Lu M.S., Electrical Engineering, University of Kentucky	7	Mr. Lu is the Senior Director of Software Quality Assurance (SQA) in the Product Management Department at AIR. He joined AIR in 2013 as a Lead SQA Engineer. Previously, Mr. Lu was a QA Manager at Fidelity Investments, where he led a test automation project in an Agile development group. He was also responsible for the design of an automated test suite for the Fidelity Portfolio Processing application.
Manoj Medarametla M.S., Software Systems, Birla Institute of Technology & Science, Pilani, India	12	Mr. Medarametla joined AIR in 2008 and is currently a Manager in the Software Development group at Hyderabad office. Mr. Medarametla is Certified Extreme Event Modeler and he holds an M.S. in Software Systems from Birla Institute of Technology & Science, Pilani, Rajasthan, India.
Ram Nagulpally M.S., Mechanical Engineering, University of Arizona	8	Mr. Nagulpally is Vice President and head of AIR's Quality Assurance group. He joined AIR in 2012. Prior to joining AIR, Ram served as a Consulting Director of Quality Assurance and Support at Reveal Data Corporation, where he successfully built a team to support the rapid growth of an early-stage startup, and he also managed delivery of the first Unicode-compliant localization product. Prior to that, he was Director of Operations for Geomagic, Inc., where he rolled out multiple versions of 3D analysis and modeling software. Ram has spent over 30 years leading engineering analysis teams in software development, professional services, and quality assurance. He holds a B.E. in Mechanical Engineering from Osmania University and an M.S. in Mechanical Engineering (Structural Mechanics) from the University of Arizona.

2.A.5. Computer/ Information Science: Name, Education	Years at AIR	Relevant Experience
Anup Rajashekharan Nair MBA, Business Analytics from Alliance University, India	1	Mr. Nair is the Manager of Model Quality Assurance team and joined AIR during Dec 2019. He is holding Engineering Degree in Civil Engineering from Government Engineering College, Kerala. Prior joining to AIR, he worked with Chubb Insurance as Account Operation Manager and with RMS India as Project Lead.
Gayatri Natarajan B.S., Electronics and Communications Engineering, Madras University, India	14	Ms. Natarajan is Vice President in the Product Management department at AIR. As Product Manager for Touchstone she manages product releases, leads the scoping and requirements for the implementation of models, analytics and hazard layers, and coordinates development activities and delivery of software products to completion. Ms. Natarajan also leads other Touchstone enhancements such as the introduction of loss modification capabilities and comparative analytics, open platforms, transparency and other key initiatives. Ms. Natarajan received her B.S. in Electronics and Communications Engineering from Madras University in India and was awarded the silver medal for top rank in her university.
Robert Newbold M.S., Information Systems, M.B.A Boston University	18	Mr. Newbold is Executive Vice President of Business Development, Marketing, and Client Services. He is responsible for the Americas and Bermuda business development team, the global marketing team, and for providing support and client service to AIR clients in the insurance, reinsurance, securitization, and intermediary markets in the Americas and Bermuda. Rob has been involved in a wide range of consulting engagements at AIR, including loss analyses, portfolio optimizations, economic impact analyses, and the management of more than 125 catastrophe bonds. Early in his career, he coordinated all facets of catastrophe modeling for one of the largest property and casualty insurers in the industry. Mr. Newbold received an M.B.A. and an M.S. in Information Systems from Boston University's Graduate School of Management. He received a B.S. in Systems Engineering from the University of Virginia. He has achieved the designation of Certified Extreme Event Modeler by completing the requirements of the AIR Institute Certified Extreme Event Modeler Program.
Martin Partyka B.S., Economics, Boston College	2	Mr. Partyka is a Manager of Internal Audit in AIR's Research team. Currently he is responsible for reviewing required documentation, standards and files developed during each phase of the model development. Prior to joining AIR, he has worked in the Internal Audit department in various industries such as banking, healthcare and insurance.
Sudhir Kumar Potharaju B.S., Electronics and Communications, Osmania University	19	Mr. Potharaju is a Senior Vice President at AIR. He is responsible for the Software Development, Product Management, and Quality Assurance teams, providing strategic execution of AIR's product and technology roadmap, and providing overall vision and direction to these groups. Mr. Potharaju has over 15 years of experience in developing software solutions. Prior to joining AIR, Mr. Potharaju worked at the Electronics Corporation of India Ltd. (ECIL) where he led various projects in the corporate R&D and Telecommunications groups. He earned a Bachelor's degree in Electronics and Telecommunications from and an Advanced Degree in Computer Applications, specializing in performance and scalability.

2.A.5. Computer/ Information Science: Name, Education	Years at AIR	Relevant Experience
Asha Prabhu B.Tech, Computer Science and Information Technology, VNR VJIET (Affiliated to JNT University), Hyderabad	8	Ms. Prabhu joined AIR in May 2011 and is a Senior Software Engineer III in AIR's Model team. Prior to joining AIR, she had four years of experience in software development/ enhancement using Microsoft Visual C++ (MFC) and SQL.
Andrew Rahedi M.A., Physics, Wesleyan University	13	Mr. Rahedi is the Director of the Core Quality Assurance Team. He joined AIR in 2008 as a Core Quality Assurance Associate in the Product Management group. Previously he was with the Hartford Life Insurance Company, where he worked as a Statistical Modeler. Andrew holds an M.A. in Physics from Wesleyan University.
Barbara Rosenstroch M.Engr, Nuclear Engineering and Applied Physics, Cornell University	8	Ms. Rosenstroch is a Principal Technical Writer in the Product Management Group. She is responsible for the development and maintenance of the Computer/Information Standards documentation for the Florida Commission on Hurricane Loss Projection Methodology process. In addition, she is in charge of the Using the Model in Touchstone series of documents, as well as the model documentation for the AIR Hurricane Model of the United States, AIR Hurricane Model for Offshore Assets, AIR China Typhoon Model, AIR Japan Typhoon Model, and the Model Builder documentation. She joined AIR in January 2012. Before joining AIR, she worked as a Senior Technical Writer at Nokia Inc. in Burlington, MA where she managed and created content for the Web Developer's Library. Also at Nokia, she held the position of Senior UI Designer, designing new features for mobile phone applications software. Ms. Rosenstroch earned a Master of Engineering degree in Nuclear Engineering and Applied Physics from Cornell University and a Bachelor of Science degree in Nuclear Engineering from Columbia University. She had a 20- year career as a nuclear engineer, performing radiation protection and shielding analyses for nuclear power plants, as well as leading projects in spent fuel storage, radioactive waste disposal, and decontamination and decommissioning and authoring consulting studies for clients.
Indumathi Sagyari B. Tech, Computer Science, JNT University, Hyderabad	13	Ms. Indumathi Sagyari is a Team Lead Engineer working in the Model Implementation Group. She joined AIR's Hyderabad Office in January 2008 as a Senior Software Engineer. Prior to joining AIR, she was working with CMC Ltd, (A TATA Enterprise) as Software Engineer where she has done projects on Defense Domain in VC++, Oracle 10g, UML etc., her academic projects include Video Conferencing, Messaging Service etc., using Java technologies.

2.A.5. Computer/ Information Science: Name, Education	Years at AIR	Relevant Experience
Praveen Sandri Ph.D., Civil Engineering, Texas Tech University	23	Dr. Sandri is the Executive VP and the Managing Director of AIR's office in Hyderabad, India. He is responsible for the strategic management of the Indian Operations which provides services in the areas of software development, model implementation, GIS, model and product testing, analytics and data services along with providing client services and business development initiatives in India and the Middle East regions. He has more than 20 years of experience in probabilistic risk analysis for natural and man-made catastrophes and has been instrumental in the development of various catastrophe models worldwide. At AIR, he specialized in structural and wind engineering aspects of the AIR hurricane modeling technology. Prior to joining AIR, Dr. Sandri was a research associate at the Wind Engineering Research Center of Texas Tech University where he worked in wind engineering and was the Manager of the Wind Engineering Research Field Laboratory (WERFL). He applied expert systems and artificial neural networks to wind engineering applications. He was the project leader for the development of WIND-RITE™, a knowledge-based expert system for the Insurance Institute for Property Loss Reduction, and he developed the "Expert System as an Alternate Code Compliance Methodology" for the Florida Housing Finance Agency.
Scott Sperling B.A., Economics, Boston University	8	Mr. Sperling joined AIR in 2012 as a Core QA Associate in the Product Management department. He previously worked for the Massachusetts Division of Banks conducting on-site examinations of banks' financial books and internal models. Scott holds a B.A. in Economics with a minor in Statistics from Boston University.
Apoorv Srivastav MBA, Birla Institute of Management and Technology, Noida, India	6	Mr. Srivastav joined AIR in Jan 2014 as Risk Analyst 1 in the Model Quality Assurance Group and is now a Sr. Model QA Analyst II. He has completed his bachelors from Commerce from Lucknow Christian College, Lucknow, India. He has also completed his Master of Business Administration from Birla Institute of Management and Technology, Greater Noida, India- with a specialization in Insurance Business Management Domain. During his 6+ Years career is AIR he has gained knowledge on all the Different Models & perils supported by AIR & also has good experience in working on Custom Projects.
Ashwin Kasilingam Thillai Natarajan M.S., Industrial Engineering, Northeastern University	5	Mr. Thillai Natarajan joined AIR in 2015 and is a Core QA Associate III in the Core Quality Assurance Team. He is responsible for validating the vulnerability module of atmospheric peril models. Prior to joining AIR, Mr.Thillai Natarajan worked as Data science Intern at New England Bio Labs, Ipswich MA. Prior to that he worked as Quality Assurance associate at MAHLE IPL Ltd., Chennai, India. He holds a master's degree in Industrial Engineering from Northeastern University, Boston and a Bachelors in Engineering in Mechanical Engineering from Anna University, India.
Srinivas Thoudoju Bachelor of Technology, SRTIST, Nalgonda	11	Mr. Thoudoju is a Lead Engineer in the Software Development Group in AIR's Hyderabad office. Prior to joining AIR, he worked as a Release Engineer for Broadridge Financial Solutions.
Ramesh Ummati M.S., Earthquake Engineering, Indian Institute of Technology, Roorkee	14	Mr. Ummati is a Senior Principal Engineer in the Model QA group at AIR Hyderabad. He plays a lead role in all aspects of testing the Hurricane Model for the United States in Touchstone. He currently plays an important role in all aspects of product testing, including updating test plans and addressing critical components of the product. He received his B.S. degree in Civil Engineering and his master's degree in Earthquake Engineering, specializing in Structural Dynamics. Prior to joining AIR, Mr. Ummati worked as an Assistant Executive Engineer in Panchayat Raj (Government Organization) Engineering Department.

2.A.5. Computer/ Information Science: Name, Education	Years at AIR	Relevant Experience
Satish Vootukuru M.S. in Information Technology (MSIT), International Institute of Information Technology (IIIT), Hyderabad	5	Mr. Vootukuru is a Senior Software Engineer I in the Model Implementation Group at AIR Hyderabad, working on implementing the Hurricane Model for the United States, as well as other AIR models, in Touchstone. Prior to joining AIR, he worked at Enhance Edu as a website developer. He completed a Master of Science in Information Technology in 2015 from IIIT, Hyderabad with an E-Business Technologies specialization.
Yingqun Wang M.S., Computer Science, California State University	13	Ms. Wang joined AIR in 2007 and is a Director in the Software Development group. She now is a team lead within the Touchstone Software Development group. She previously worked as a Programmer Analyst at the University of California. Ms. Wang holds an M.S. in Computer Science from California State University in San Bernardino, CA.
David Wilson MBA., Wallace E. Carroll Graduate School of Management, Boston College	17	Mr. Wilson is a Director in the Product Management group at AIR. He manages various feature enhancements for AIR catastrophe risk products, including various workflow enhancements, geocoding enhancements, updates to the supported administrative and postal boundary data, and updates to property-specific databases. He also manages various third-party licensing activities for the PM group. Prior to joining AIR in 2003, Mr. Wilson worked as a Product Manager at Vality Technology (now part of IBM) as a Product Manager for data quality and geocoding products. He received his B.Sc. degree in Mathematics from the State University of New York at Albany, and his MBA. from the Wallace E. Carroll Graduate School of Management at Boston College.

2.A.6. Data Management and Exposures: Name, Education	Years at AIR	Relevant Experience
Anthony Hanson M.A., Economics, Boston College	15	Anthony Hanson is a Director of Analytics in the AIR Exposures group where he assists in the development of AIR's global industry exposure. Some past projects include, modeling the value of Canadian infrastructure (transportation, utilities and communications), modeling the value of industrial facilities (manufacturing, mining and energy) for the industry exposure, and most recently researching global demand surge and its impact on losses. He earned his B.A., summa cum laude, in Economics from the University of Massachusetts and an M.A. in Economics from Boston College.
Cheryl Hayes M.A., Environmental Studies, Boston University	20	Ms. Hayes is a Vice President and manager of the Exposures, Data Management, Audit and Operation teams in the Research and Modeling Group. During her tenure at AIR, she has led a multi-disciplinary team in the development of comprehensive, high resolution industry exposure databases for more than 100 countries worldwide. She has also been instrumental in streamlining the development process for the industry exposure databases, and has worked to advance the quality of the industry exposures. In addition, she has been involved in numerous consulting and special projects, including catastrophe bonds and the FEMA Flood Insurance Risk Study. Prior to joining AIR, Cheryl worked at Liberty Mutual as an analyst in the environmental department. Ms. Hayes holds her B.A. in Political Science from Mount Holyoke College and her M.A. in Environmental Studies from Boston University.

2.A.6. Data Management and Exposures: Name, Education	Years at AIR	Relevant Experience
Aaron Knox B.S., Computer Science and Economics, Rose-Hulman Institute of Technology	1	Mr. Knox joined AIR in 2019 a Senior Analyst I in the Data Management Group. His primary focus has been to streamline our AIRFlow automatic data downloads by developing a comprehensive suite of database onboarding and validation processes, including a web-based dashboard that monitors data downloads in real-time. Prior to joining AIR, Aaron worked at State Street Corporation as an assistant vice president in the Global Markets division. He earned his B.S. in both Computer Science and Economics from the Rose-Hulman Institute of Technology.
Katherine Landesman M.S., Geographic Information Sciences, Clark University	3	Ms. Landesman joined AIR in 2017 and is a Senior Analyst I in the Data Management Group. Since working at AIR, she has been instrumental in creating on-demand maps for AIR's ALERT postings, coordinating and standardizing data storage and documentation processes between departments, and scripting AIRFlow real-time data downloads. Prior to joining AIR, she worked on earning both her B.A. in Global Environmental Studies and her M.S in Geographic Information Science from Clark University.

2.A.7. Editorial: Name, Education	Years at AIR	Relevant Experience
Heidi H. Carrell B.A. English (Hons.) University of New Hampshire	3	Ms. Carrell is a Senior Writer in AIR's Marketing Communications. She is a communications professional with over 15 years of writing, editing, publications management, and research support, including coordinating research grant applications. Prior to joining AIR, she was Communications Manager at Harvard's Joint Center for Housing Studies, where she managed the State of the Nation's Housing and other research publications. Before that, she was Lab Coordinator for the E.J. Safra Center for Ethics, an interdisciplinary research center at Harvard Law School, where she edited the working paper series and managed over 300 applications yearly for U.S. and international professional fellowships.

Executive Summary

This document provides an overview of AIR's Individual Risk Module (IRM) for modeling the impact of secondary risk characteristics on damageability and insured hurricane losses in the United States. The capability is part of the vulnerability component of the AIR Hurricane Model for the U.S. and is included in AIR's detailed loss estimation software, Touchstone®. This document facilitates a better understanding of the impact of secondary building and environmental features on damage and loss. It will also assist clients in deriving mitigation factors to be used for property loss costs.

AIR's approach is an engineering based framework designed to estimate the performance of residential and commercial buildings under wind loads. It is based on engineering principles and data regarding building performance during high winds.

The general, or base, damage functions used by the AIR Hurricane Model for the U.S. are individually developed for the "typical" building with certain "primary" risk characteristics, which include age, height, construction type and occupancy class. The construction and occupancy classes are broadly defined, without reference to individual—or secondary—structural characteristics. AIR's general damage functions were validated and calibrated using extensive and detailed actual hurricane loss data. The relative abundance of hurricane loss data greatly facilitates the determination of average or "typical" building performance.

Modification functions (or secondary risk characteristics) are applied to the general damage functions to reflect the performance enhancement or diminution of a wide variety of secondary structural and environmental characteristics. These might include roof covering, roof pitch, type of window protection or proximity to trees (which are potential sources of wind-borne missiles). Detailed claims data from 2004 and 2005 storms have been used to validate the impact of these secondary risk characteristics on building vulnerability.

The modification functions referenced above reflect the difference between the performance of a building with known structural and environmental characteristics and that of the typical building. For example, the modification function for a residential wood frame building with hip roof indicates how it would perform differently from a typical residential wood frame building whose roof is mathematically defined to exhibit average performance.

The modification functions are themselves functions of wind speed. That is, the effectiveness of mitigating characteristics varies according to the wind speed. In addition, the combined effect of the modification functions for different secondary risk characteristics is complex and not necessarily additive or multiplicative.

The marginal impact of secondary risk characteristics on building vulnerability is dependent on the year that the structure was built and on its location. This is due to the fact that for a class of structure, the AIR Hurricane Model for the U.S. defines a *typical* building in terms of *typical* secondary risk characteristics for each location and year built. User input of secondary risk characteristics will overwrite the *default secondary risk characteristics*, and a new vulnerability function is created. The new function may reflect lower or higher vulnerability than the default, depending on the effect of user's input relative to default features.

For example, if a user inputs "engineered shutters," this will result in no, or minor, reductions in vulnerability for a home built in Miami after 2002 but a large reduction in vulnerability for a home built before 1995 in Tallahassee, Florida. This coherent, logic-based approach provides a framework that properly accounts for the overlap of the impact of different secondary features (e.g., year built and mitigation features), and avoids potential double-counting of secondary features in the model.

©2019 AIR Worldwide

The AIR methodology follows a structured approach to quantify the impact of more than 25 secondary risk characteristics, covering a range similar to that in the public domain—and, in particular, that used in the Florida Department of Community Affairs (DCA) study. Touchstone users may use these factors to develop rating credits in a manner similar to the one presented in this document.

Introduction

The AIR Hurricane Model for the U.S. in Touchstone includes the capability to account for the impact of secondary building and environmental characteristics on the vulnerability of individual risks. The modeling methodology was developed using an engineering-based framework in a structured approach.

Based on structural engineering expertise and building damage observations made following historical hurricanes, more than 25 building features (see Table 1) have been identified as having a significant impact on building damage and losses. Options corresponding to each feature (see Table 7) are identified based on construction practice. Algorithms for modifying the damage functions are developed based on engineering principles and observational data. The AIR Hurricane Model for the U.S. in Touchstone supports any combination of multiple building features and produces a modification function that is applied to the base vulnerability function. The modification function captures the changes to building vulnerability that result when certain building features are present, and when information on such building features is known. The modification function varies with wind intensity to reflect the relative effectiveness of a building feature when subject to different wind speeds.

This document provides a brief overview of the component parts of all AIR natural hazard peril models, followed by a more detailed overview of the damage estimation, or vulnerability, component. That section is followed by details regarding wind-induced loads and resulting damage, a discussion of building and environmental features that affect building performance, and information on AIR's development of loss modification factors for a range of building features similar to those used in the Florida public domain study.

Overview of AIR Catastrophe Modeling Technology

Figure 1 illustrates the components of AIR's catastrophe models. In the case of the AIR Hurricane Model for the U.S., the "Event Generation" module is used to create the stochastic storm catalog. More than one hundred years (1900-present) of historical data regarding the frequency of hurricanes and their meteorological characteristics are used to fit statistical distributions for each model parameter, including landfall location and storm heading at landfall, and the intensity variables of central pressure, radius of maximum winds, forward speed, and storm track. By stochastically drawing from these distributions, the fundamental characteristics of each simulated storm are generated. The result is a large, representative catalog of potential events.

©2019 AIR Worldwide

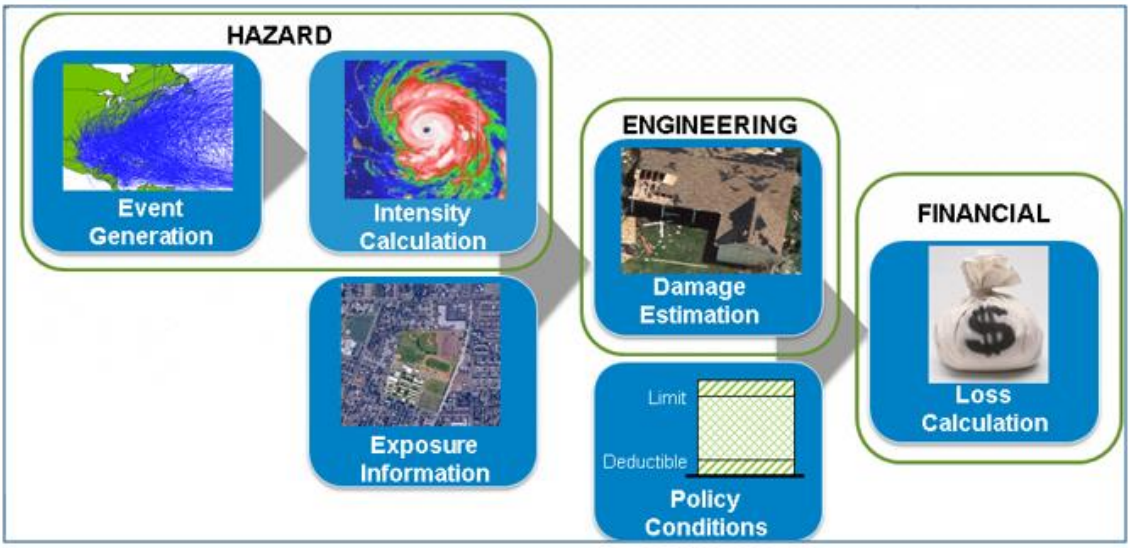

Figure 1. Components of an AIR Catastrophe Model

Once values for each of the important meteorological characteristics have been stochastically assigned, each simulated storm is propagated along its track. Peak 1-minute sustained wind speeds and wind duration are estimated for each geographical location affected by the storm to calculate "Local Intensity."

The "Damage Estimation" component of the model overlays the local intensity of the simulated event onto a database of exposed properties. The model then calculates the resulting monetary damage by applying damage functions, which capture the effects of the intensity of the event, which varies by location, on exposed buildings. Separate damage functions are developed for different construction types and occupancy classes. Similarly, separate damage functions for each of building, contents, loss of use, and business interruption are applied to the replacement value of the insured property to calculate losses for these coverages.

Finally, the "Insured Loss Calculation" is made by applying the policy conditions to the total damage estimates. Policy conditions may include deductibles by coverage, site-specific or blanket deductibles, coverage limits and sublimits, loss triggers, coinsurance, attachment points, and limits for single or multiple location policies, and risk specific reinsurance terms.

After all of the insured loss estimations have been completed, they can be analyzed in ways of interest to risk management professionals. For example, the model produces complete probability distributions of losses, or exceedance probability curves, for gross and net losses and for both annual aggregate and annual occurrence losses. Output may be customized to any desired degree of geographical resolution down to location level, as well as by line of business, and within line of business, by construction class, coverage, etc. The model also provides summary reports of exposures, comparisons of exposures and losses by geographical area, and detailed information on potential large losses caused by the extreme events that make up the tail of the distribution.

Damage Estimation Overview

The **Damage Estimation** component of the AIR Hurricane Model for the U.S. applies the local intensity of the simulated event to a database of exposed properties. The model determines damage estimation through the use of damage, or vulnerability, functions, which illustrate the interaction between buildings (and contents) and the local intensity to which they are exposed.

©2019 AIR Worldwide

Uncertainty in damage comes from many sources including variability in the strength of building components and variability in building features as well as the level of uncertainty in the local intensity at the location under consideration. Further, uncertainty in the human response (whether windows are covered, for example) can significantly affect the damage severity. As claims analyses indicate that a single parametric distribution cannot be used to model the variability in the flood damage data, AIR engineers use a combination of beta and Bernoulli probability distributions (also called an “inflated beta” distribution) to capture the uncertainty in damage at a location.

The damage functions relate the mean damage level, as well as the variability of damage, to the measure of intensity at each location. That is, the AIR Hurricane Model for the U.S. estimates a complete distribution around the mean level of damage, for each local intensity and each type of structure. Because different structure types will experience different degrees of damage, the damage functions vary according to construction and occupancy. Losses are calculated by applying the appropriate damage function to the replacement value of the insured property.

The AIR damage functions incorporate the results of well documented engineering studies, tests, and structural calculations. They also reflect the relative effectiveness and enforcement of local building codes. AIR engineers refine and validate these functions through the use of post-disaster field survey data and through an exhaustive analysis of detailed loss data from actual events.

Separate damage functions for buildings, contents, and time element provide not only estimates of the mean, or expected, damage ratio corresponding to each wind speed, but also probability distributions around each mean. In the case of building damageability, the damage ratio is the dollar loss to the building divided by the corresponding replacement value of the building. As can be seen in Figure 2, the model ensures non-zero probabilities of zero and one hundred percent loss (for individual properties).

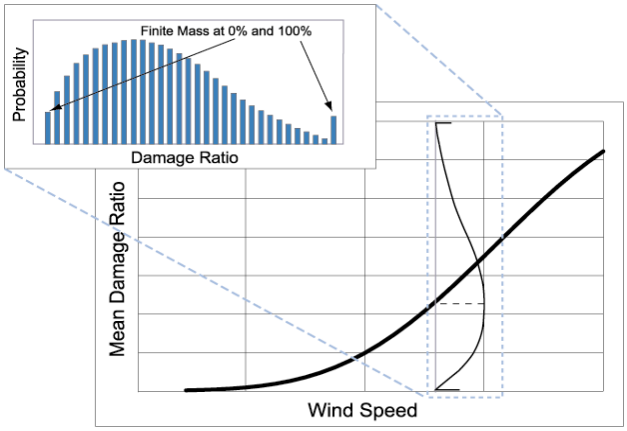

Figure 2. Representative Damage Function

AIR damage functions have been extensively validated using detailed actual loss data provided by a number of clients for various storms. Validation is performed by comparing simulated and actual losses for client companies by state or county, and line of business. Using detailed data, AIR has fine-tuned of damage ratios by construction class, coverage type, and wind speed.

Accounting for Secondary Risk Characteristics

Wind Induced Loads

Winds that are close to the earth’s surface are subjected to frictional drag from the terrain roughness. As the distance from the surface increases, these frictional effects decrease and, at a

©2019 AIR Worldwide

certain height, become negligible. The height at which the surface roughness is negligible is referred to as the *gradient height*. The layer of air below this height, where the wind is turbulent and its speed increases with height, is known as the atmospheric boundary layer, whose height ranges from the ground surface to between 1,000 and 2,000 feet. All structures are located in this atmospheric boundary layer and act as bluff bodies to wind.

When wind comes into contact with buildings, the airflow streamlines separate at the sharp corners of buildings such as wall corners, eaves, roof ridges and roof corners (Figure 3). This separation induces additional turbulence in airflow causing highly fluctuating pressures on the building surfaces. The direction of wind with respect to the building (angle of attack) is also a significant factor in the magnitude and fluctuation of pressures acting on the surfaces of the building.

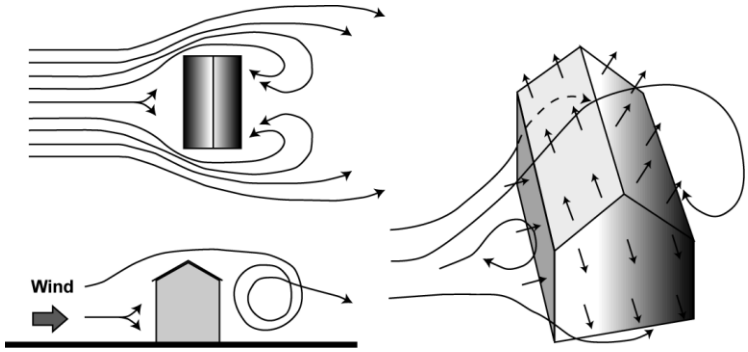

Figure 3. Wind Flow Around Buildings Can Generate Severe Pressure and Suction Forces

In general, when wind acts on a building, the windward wall experiences a pressure pushing inward (positive pressure) while the sidewall and the leeward wall will experience a suction pressure outward (negative pressure). The roof, depending on its slope, will experience uplift (negative pressure). Wind forces are significantly increased at corners, ridges, and at abrupt changes in the direction of wind flow.

Two important flow mechanisms with respect to buildings are discussed below.

Flow Separation

When wind impinges the front wall, it flows upward past the roofline. The wind is unable to turn abruptly at the roofline and so continues past the roof edge, thus separating from the roof eave. Suction forces are often found on the roof under the separated flow, especially near the separation point. The wind that has separated slowly comes back to its original flow direction there by reattaching on the roof surface. The point of reattachment depends on the dimensions of the buildings, roof geometry, the wind speed, and wind direction relative to the building.

Roof Corner Vortex

Wind approaching the roof corner at a quartering angle flows up over the roof, and rolls up into two vortices of opposite rotational directions originating at the building corner. These vortices are much like miniature tornadoes, producing high speeds under the vortices. These roof corner vortices are sometimes called the delta wing vortices (Figure 4).

©2019 AIR Worldwide

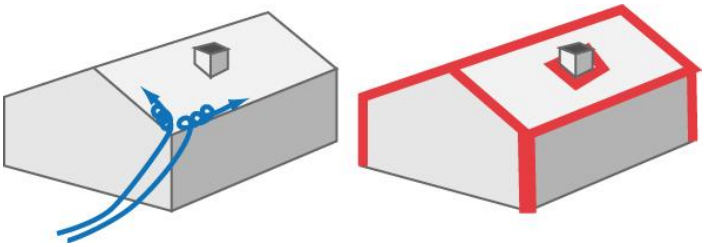

Figure 4. Wind Flow Separation Around Roof

Wind Damage

Damage surveys traditionally classify buildings as either engineered or non-engineered. An engineered building will generally have less susceptibility to wind damage than a non-engineered building. Most residential dwellings are classified as non-engineered. An example is a wood-frame single-family dwelling, which may not have received attention from a structural engineer during construction. Commercial structures that are built in accordance with building codes and under the supervision of a structural engineer are classified as engineered. A typical engineered structure is a high-rise reinforced concrete building.

Wind Damage to Non-Engineered Buildings

Figure 5 illustrates the dynamic process by which non-engineered buildings are damaged by wind. Wind primarily affects non-structural elements, such as different components of the building envelope. In most cases, damage is fairly localized. Roofs and openings in the façade (e.g., windows and garage doors) are typically the first elements to be damaged. Loss of the first shingle allows wind to penetrate and lift the next shingle. Unsecured slates may peel off; metal roofs may roll up and become detached.

Damage accelerates as wind speeds increase. The loss of the first window, either because of extreme pressure or of wind-induced projectiles, can create a sudden build-up of internal pressure that can lift a roof system off the building from inside, even if it is properly secured.

At high wind speeds, the integrity of the entire structure can be compromised, particularly in cases where the roof provides lateral stability by supporting the tops of the building's walls. Structural collapse may occur during extreme wind events. Even if the structure remains intact, once the building envelope is breached, contents are vulnerable to wind as well as accompanying rain.

©2019 AIR Worldwide

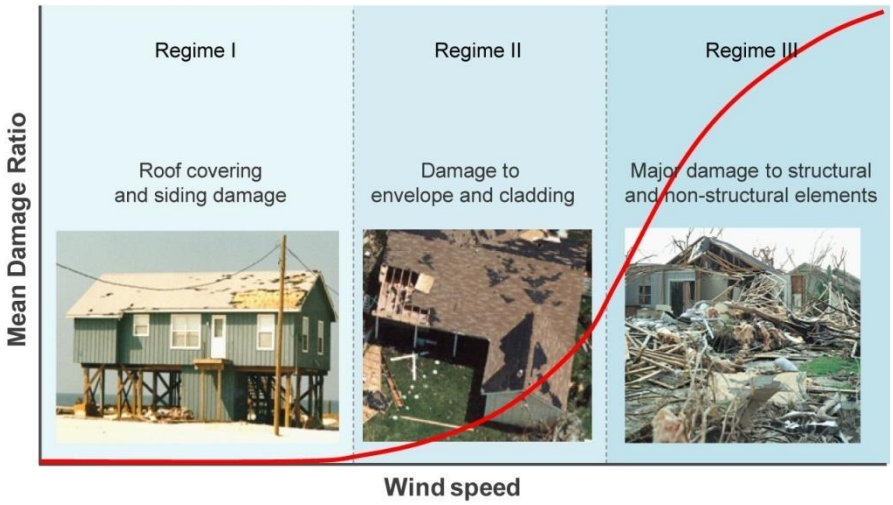

Figure 5. Damage Profile of Non-engineered Buildings

Wind Damage to Engineered Buildings

For engineered buildings, damage typically occurs to the following building (non-structural) components:

- Mechanical equipment
- Roofing
- Wall cladding
- Breaching of doors and windows

Complete structural collapse is a rare for well-engineered buildings. Even so, damage to non-structural components of a building can add up to a significant financial loss.

Examples of typical damage patterns can be seen in Figure 6.

Figure 6. Damage to (a) Mechanical Equipment, (b) Roof, (c) Cladding, and (d) Windows

©2019 AIR Worldwide

Building and Environmental Features

AIR accounts for the impact of secondary building and environmental characteristics, or features, on the wind vulnerability of individual risks. The methodology was developed at AIR using a structured, engineering-based framework that is based on structural engineering expertise and building damage observations made in the aftermath of actual hurricanes.

In the AIR Hurricane Model for the U.S., options for each characteristic are identified based on construction type. Algorithms for modifying the vulnerability functions, for both structural and nonstructural damage, are developed based on engineering principles and observations of building performance. The AIR Hurricane Model for the U.S. supports the effects of any combination of building features on the building damage and produces a modification to the vulnerability function. The modification function captures the changes to building vulnerability that result when certain building features are present and when information on such building features is known. The modification function varies with wind intensity to reflect the relative effectiveness of a building feature when subjected to different wind speeds.

Figure 7 illustrates the application of modification factors to the basic damage functions.

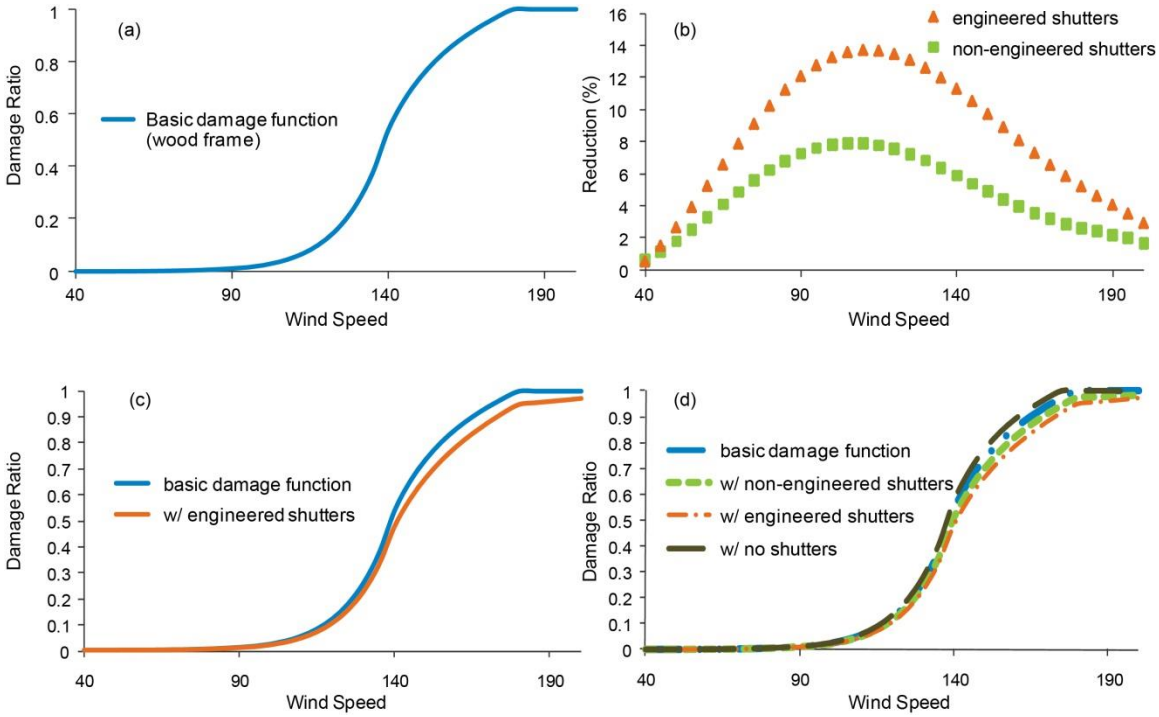

Figure 7. (a) Basic Damage Function for Wood Frame Construction; (b) Reduction in Damage for Engineered vs. Non-Engineered Shutters; (c) Basic Damage Function and Modified Function for Engineered Shutters; (d) Envelope of Damage Functions, All Protection Options

Individual Risk Features (Secondary Risk Characteristics)

The first step in the development of the modification functions is the identification of building and environmental characteristics that impact the performance of a building in high winds. These features are selected based on research and damage surveys, which detail building performance in high wind. Some can be categorized as non-structural (cladding, for example), while others are structural (roof and wall systems, for example); still others address very general features such as

©2019 AIR Worldwide

building condition and, finally, environmental features include such things as the proximity to trees.

The building characteristics supported in the AIR Hurricane Model for the U.S. are shown in Table 1. For each of these, various options are available, as discussed below. For the AIR Location Detail Codes, see the latest version of the *Touchstone® Exposure Data Validation Reference*, which is available at http://www.air-worldwide.com/Documentation/Validation/6.0/index.htm.

Table 1. Secondary Risk Characteristics Supported by the AIR Hurricane Model for the United States in Touchstone

Secondary Risk Characteristics	
Adjacent Building Height	Roof Covering
Appurtenant Structures	Roof Cover Attachment
Building Condition	Roof Deck
Certified Structures	Roof Deck Attachment
Exterior Doors	Roof Geometry
Floor of Interest	Roof Pitch
Foundation Connection	Roof Year Built

Project Phase	Wall Attached Structures
Roof Anchorage	Wall Type
Roof Attached Structures	Wall Siding
	Window Protection

Appurtenant Structures

An appurtenant structure is a building that is located on a property but is not an integral part of the main building. Appurtenant structures may require a different treatment in analysis from the main building. For example, a pool enclosure may provide protection of a recreational pool from everyday wind and sun exposure. However, if winds are high enough to damage the main building, then the pool enclosure may become flying debris, and increase the amount of damage to the main building. The following appurtenant structures can be entered:

- Unknown/default
- Detached garage
- Pool enclosure
- Shed
- Masonry boundary wall
- Other fence
- No appurtenant structures
- No pool enclosure

©2019 AIR Worldwide

Adjacent Building Height

This entry describes average height of buildings adjacent to the building of interest. Building height is expressed as the number of stories, with the default (0) indicating unknown height. For the hurricane peril, this field is in conjunction with Floor of Interest and Terrain Roughness.

Building Condition

This condition assessment of a building is based on its external appearance. The condition of the outside of the building and its maintenance, described as good, average, or poor, is used to determine a estimate of expected performance. Buildings with signs of distress or duress are likely to experience additional damage during a hurricane. Some examples of these signs are: an aging roof, aging exterior walls or cladding; loose roof tiles or chimney damage; or damage from previous hurricanes.

Foundation Connection

This describes the connection type between the structure and foundation and is a critical factor in single-family dwellings made of wood-frame and tilt-up construction. The connection transfers the vertical and lateral loads on the building to the foundation during wind events. The valid entries are:

- Unknown/default
- Hurricane ties
- Nails/Screws
- Anchor Bolts
- Gravity/Friction
- Adhesive/Epoxy
- Structurally connected

For Industrial Facilities (occupancy classes between 400 - 488), this field represents the anchorage of equipment at the facility. The valid entries are anchored, unanchored, or unknown anchorage.

Certified Structures

Fortification standards were developed by the Insurance Institute for Business Home and Safety (IBHS). They are designed to help strengthen homes and businesses through retrofitting and new construction standards to improve their strength and resistance to natural perils.

Residential and commercial buildings that meet certain levels of standards are eligible for gold, silver, or bronze certification, which represent the level of disaster protection. The supported entries are:

- Unknown/default
- Fortified Home™/Business (IBHS) Bronze Option 1
- Fortified Home™/Business (IBHS) Bronze Option 2
- Fortified Home™/Business (IBHS) Silver Option 1
- Fortified Home™/Business (IBHS) Silver Option 2
- Fortified Home™/Business (IBHS) Gold Option 1
- Fortified Home™/Business (IBHS) Gold Option 1
- Fortified for Safer Living®/Safe Business (IBHS)

©2019 AIR Worldwide

Exterior Doors

Exterior doors, and the frames that hold them, are weak in resisting wind loads. They deflect considerably under high wind loads and thus fail. This entry describes the type of exterior doors in the building as different types have different amounts of wind resistance. The valid entries are:

- Unknown/default
- Single width doors
- Double width doors
- Reinforced single width doors
- Reinforced double width doors
- Sliding doors
- Reinforced sliding doors

Floor of Interest

Different floors of a building experience varying degrees of damage as well as different types of damage. This entry identifies the floor concerned, if coverage is not for the entire building. Replacement values (building, contents, and BI) as well as policy terms should be entered for the floor of interest and not the whole building. This field should be used in conjunction with the Terrain Roughness and Average Adjacent Building Height.

Glass Percentage

In general, the greater the percent of glass in a wall, the greater the wall's vulnerability to damage. This entry represents the percentage of the wall area that is glass.

- Unknown/default (or no floor of interest)
- Less than 5%
- 5% to 20%
- 20% to 60%
- Greater than 60%

Glass Type

Different types of glass have different levels of resistance to wind loads and debris impact. The valid entries for glass type are:

- Unknown/default
- Annealed
- Tempered
- Heat strengthened
- Laminated
- Insulating glass units

Large Missile Source

A source of a large missile is any object within 100 feet of the property that could potentially become large flying debris in hurricane winds and breach the building envelope. Examples of large missile sources include outdoor furniture, loose boards or building materials, or wood planks or studs on nearby buildings that can become dislodged in high winds.

©2019 AIR Worldwide

Project Completion Percentage

This percentage applies to Average Project Loss at Phase 5 for builder's risk policies, or the average loss over the duration of the project. It indicates the percentage of the project (0%-99%) that is completed at the start of the policy and is determined by the cost of the project. If no builder's risk is selected then other phase losses are selected and the percentage complete entry will be ignored.

Project Phase

For builder's risk policies, this secondary feature can be used to identify the phase of construction that is currently underway. If no builder's risk is selected (0), then construction is assumed to be complete and regular risk is applied. Buildings under construction have varying degrees of vulnerability that depend on the construction phase:

- No builder's risk/default
- Phase 1: Foundation and Substructure
- Phase 2: Superstructure
- Phase 3: Walls and Roofing
- Phase 4: Interior, Mechanical (Conveying, Plumbing, HVAC, Fire Protection, Electrical, Furnishings, Misc.
- Phase 5: Average Project Loss (the average loss over the duration of the project)
- Worst Loss: The project phase when the loss potential is highest.

Roof Anchorage

The type of connection that secures the roofing support to the walls affects how well wind loads are transferred to the walls, reducing the vulnerability of the roof. The anchorage types are:

- Unknown/default
- Hurricane ties
- Nails or Screws
- Anchor bolts
- Gravity or Friction
- Adhesive epoxy
- Structurally connected roof
- Clips

Roof Attached Structures

Structures that are attached to a property's roof, such as mechanical equipment, may be more vulnerable to winds than the main building, particularly if they are not well anchored. Some roof attached structures help protect the roof from damage. Supported roof attached structures are:

- Unknown/default
- Chimneys
- Air conditioning units
- Skylights
- Parapet walls
- Overhang/Rake
- Dormers
- Waterproof membrane/fabric
- Secondary water resistance (e.g., bitumen tape)
- Other

©2019 AIR Worldwide

Roof Covering

The material used for the roof covering has a significant impact on the roof's ability to resist wind damage. If the roof covering is damaged, then the interior of the building and its contents become more vulnerable. Supported roof covering materials are:

- Unknown/default
- Asphalt shingles
- Wood shingles
- Clay/concrete tiles
- Light metal panels
- Slate
- Built-up roof with gravel
- Built-up roof without gravel
- Single ply membrane
- Single ply membrate ballasted
- Standing seam metal
- Hurricane wind rated roof covering

Roof Cover Attachment

The type of connection that secures the roof covering to the roof deck affects the roof's vulnerability to wind. Attachments that become damaged due to high winds can increase the vulnerability of the roof covering. Supported roof covering attachments include:

- Unknown/default
- Screws
- Nails/staples
- Adhesive/epoxy
- Mortar

Roof Deck

The roof deck material affects how well wind loads are transferred from the roof to underlying joists and purlins. A damaged roof deck results in a breached building envelope, which causes significant building and contents damage. Supported roof deck materials are:

- Unknown/default
- Plywood
- Wood planks
- Particle board/OSB
- Metal deck with insulation board
- Metal deck with concrete
- Pre-cast concrete slabs
- Reinforced concrete slabs
- Light metal

Roof Deck Attachment

The type of connection that secures the roof deck to the underlying roof system affects the roof's vulnerability to wind. Attachments that become damaged due to high winds can increase the vulnerability of the roof deck. Supported roof covering attachments include:

- Unknown/default
- Screws/bolts
- Nails
- Adhesive/epoxy
- Structurally connected
- 6d nails @ 6" spacing, 12" on center
- 8d nails @ 6" spacing, 12" on center
- 8d nails @ 6" spacing, 6" on center

Roof Geometry

The shape of a roof has a significant effect on its wind vulnerability. Wind vortices at the corners result in suction forces that can lift the roof. Large complex roof geometries tend to reduce the intensity of the wind pressure and the resulting uplift forces. The supported roof geometries are:

- Unknown/default
- Flat
- Gable end without bracing
- Gable end with bracing
- Hip
- Complex
- Stepped
- Shed
- Mansard
- Pyramid
- Gambrel

Roof Pitch

The roof pitch refers to its slope angle, which affects the suction forces of winds. Greater roof pitches lower the uplift forces, thereby improving the wind resistance of the roof. A low pitch is under 10°, a medium pitch is between 10° and 30°, and a high pitch is a slope greater than 30°.

Roof Year Built

This secondary feature indicates the year the current roof was put in place. Roofs lose their strength over time and become more vulnerable to wind loads. Older roofing systems may not have been as well-designed for wind resistance as roofs that meet stricter code requirements. In the absence of a specified roof year built input from the user, if the structure year built is within the last ten years the roof is considered to be new.

Seal of Approval

This secondary feature accounts for the level of engineering provided to the design of a building. A fully engineered structure is one that has been designed by a Professional Engineer (PE), who is required to provide a seal of approval to the calculations and drawings of the building plan. These structures have the greatest resistance to wind loads.

A partially engineered structure is one that has been inspected by a PE who has determined the building is “deemed to comply” with the respective building code. No seal is required for a partially engineered designation. A minimally engineered structure is one that does not meet conditions well enough to warrant a seal of approval or “deemed to comply” designation.

Small Debris Source

Roof gravel, trash bins, tree branches, or other small debris can be carried aloft by high winds and breach window glass. This secondary feature indicates whether there is a potential for small debris within a radius **of 200 ft. of the building.**

Terrain Roughness

As hurricane winds travel over land, their speed can be significantly affected by the terrain. The effects of the surrounding terrain therefore greatly affect a building’s vulnerability to winds.

©2019 AIR Worldwide

Large city centers—Large city centers where at least 50% of the buildings are higher than 70 ft. (21.3 m). This exposure category is limited to areas for which terrain representative of Exposure A prevails in the upward direction for a distance of at least 0.5 mi. (0.8km), or 10 times the height of the building, whichever is greater. The model accounts for channeling effects or increased velocity pressures due to other structures situated alongside the building.

Urban, suburban, and wooded areas—Terrain with numerous closely-spaced structures the size of single-family homes or larger. This exposure category is limited to areas for which terrain representative of Exposure B prevails in the upwind direction for a distance of at least 1,500 ft. (460 m) or 10 times the height of the building or other structure, whichever is greater.

Open terrain with scattered obstructions—Open terrain and grasslands are examples of this exposure category. Structures in this category usually have heights lower than 30 ft. (9.1 m).

Flat, unobstructed areas—Buildings and other structures exposed to winds flowing over open water for a distance of at least 1 mi. (1.61 km). This exposure category extends inland from the shoreline a distance of 1,500 ft. (460 m), or 10 times the height of the building or structure, whichever is greater.

Tree Exposure

Strong winds can snap trees or blow them over, causing them to fall on nearby buildings. This can cause significant damage, particularly if they breach the building envelope. This secondary feature provides an indication of whether a falling or snapped tree hazard exists near the building.

Wall Attached Structures

Buildings may have objects that are physically attached to its exterior walls but are not an integral part of the main building structure. These attached structures are often more vulnerable than the main building, particularly if the anchorage is inadequate. They are more exposed to winds and may become dislodged and create a breach, or become flying debris. Supported wall attached structures include:

- Unknown/default
- Carports/Canopies/Porches
- Single door garage
- Reinforced single door garage
- Double door garage
- Reinforced double door garage
- Screened porches/ Glass patio doors
- Balcony

Wall Siding

The wall siding material of a building, which is used to protect the walls from weathering, affects its vulnerability to wind loads. Any breach in the wall siding can expose the wall to wind and allow pressure to build up and create more damage. Supported wall siding materials are:

- Unknown/default
- Veneer brick/masonry
- Wood shingles
- Clapboard
- Aluminum/vinyl
- Stone panels
- Exterior insulation finishing system (EIFS)
- Stucco

©2019 AIR Worldwide

Wall Type

The external wall material of a building affects its vulnerability to wind loads. Any breach in the wall can allow pressure to build up inside the building and create more damage. Supported materials are:

- Unknown/default
- Brick/unreinforced masonry
- Reinforced masonry
- Plywood
- Wood planks
- Particle board
- Metal panels
- Pre-cast concrete elements
- Cast-in-place concrete
- Gypsum board

Window Protection

This secondary feature indicates whether engineered shutters or non-engineered shutters are installed. Both types can provide window protection against strong winds, particularly engineered shutters.

Example of Secondary Risk Characteristics: Roof System

This section provides an example of how individual elements of a structural system (in this case, the roof system) combine to influence damage and loss due to hurricanes.

The main function of a roof is to enclose the building space and protect it from the damaging effects of rain, wind, heat, and snow. Consideration is also given to factors such as strength and stability under anticipated loads, heat insulation, lighting, ventilation, sound insulation, and aesthetics, etc.

In the AIR Hurricane Model for the U.S. as implemented in Touchstone, a roof system comprises the following features:

- Roof age
- Roof covering
- Roof covering attachment
- Roof deck
- Roof deck attachment
- Roof geometry
- Roof pitch

©2019 AIR Worldwide

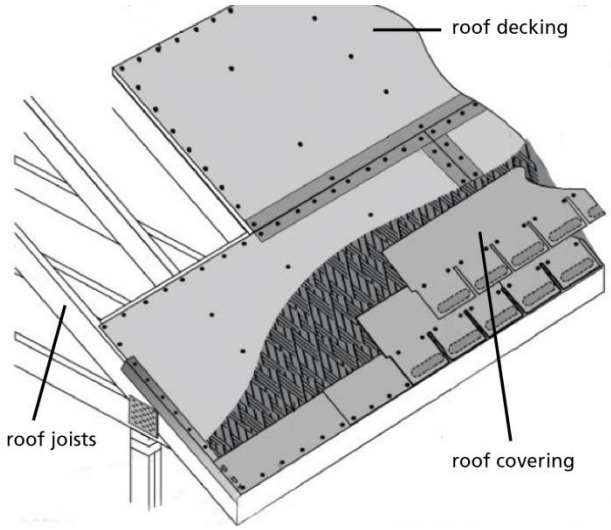

Figure 8. Some Key Components of a Roof System

Brief descriptions of some of the features that influence damageability and loss due to hurricanes are provided below.

Roof Covering

The roof covering is the material covering the framework of the roof structure in order to safeguard the roof against the weather. This material is fixed to the underlying structure by means of a range of fittings and fixtures.

Climatic conditions influence the performance and durability of roof coverings. Strong winds may dislodge certain types of roof coverings such as slates, tiles, and asphalt shingles, particularly if they are not properly affixed. Extreme temperature changes can cause the material to crack and joints to leak, if they are not properly protected. Fog, salt, or smoke and other gases can corrode metal roofing that is protected such as by being painted regularly. Rubber membranes and asphalt shingles can become brittle and crack as a result of prolonged exposure to ultraviolet radiation. The various effects described above can result in poor roof performance, reduced roof life, or both.

Roof coverings are fastened to roof decks, which are supported by structural members such as girders, trusses, or rigid frames. In the case of shell roofs, the decks serve as principal supporting members. In some cases, the roof covering and the deck are combined into one unit, such as with corrugated roofing. Because of these varying roofing systems, the type of roof covering and the type of roof deck should be selected concurrently.

The weight of the roof covering affects the design, weight, and cost of both the roof deck and its supporting structure or framework. A heavier roof covering requires a stronger supporting structure, which adds to the cost. For example, sheet metal coverings are very lightweight, and shingles can be classified as light to medium in weight, whereas clay tiles and slates are considered to be heavy roof coverings. Supporting structures and roof decks are designed according to the weight of the chosen roof covering. Figure 9 shows typical wind damage to a roof covering.

©2019 AIR Worldwide

Figure 9. Wind Damage to a Roof Covering

Roof Deck

The roof deck transfers the roof loads to the underlying trusses or rafters. Damage to the roof deck constitutes a breach of the building envelope and can result in significant building and interior damage. Some commonly used roof deck materials are plywood, precast concrete slabs, reinforced concrete slabs, and light metal. Figure 10 shows wind damage to a roof deck.

Figure 10. Wind Damage to a Roof Deck

Roof Geometry

The magnitude of aerodynamic loads that are applied to a roof is largely determined by its geometry, or shape, as it affects the intensity of wind pressures and the resulting uplift resistance. Common roof shapes include gable and hip, although a variety of roof shapes are possible. Below are some brief descriptions of more common roof shapes.

Gable Roof—A gable roof slopes in two directions so that the end formed by the intersection of the slopes is a vertical triangle (Figure 11).

©2019 AIR Worldwide

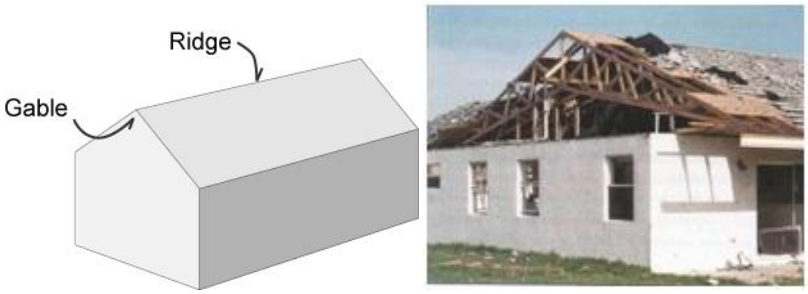

Figure 11. Illustration of a Gable Roof and Hurricane Damage

-

Hip Roof—A hip roof slopes in four directions so that the end formed by the intersection of the slopes is a sloped triangle (Figure 12).

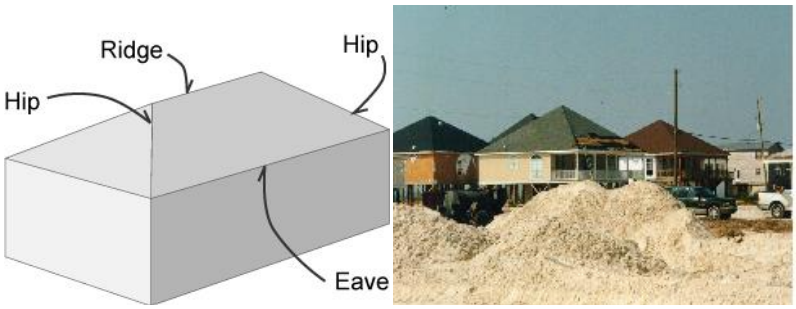

Figure 12. Illustration and Examples of Hip Roofs

Mansard Roof—Like the hip roof, this roof also slopes in four directions but there is a break in each slope (Figure 13).

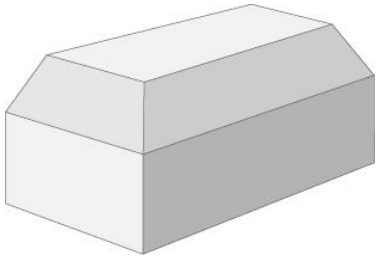

Figure 13. Illustration of a Mansard Roof

Methodology for Accounting for Secondary Risk Characteristics

Building aerodynamics is a complex phenomenon due to the fact that the performance of a building depends on the interaction of several building components. Moreover, damage due to wind is progressive: failure at a localized level can eventually grow to a catastrophic level. Thus it is important to recognize the way in which damage progresses and the role and importance of building components at each stage of failure.

AIR's methodology for accounting for secondary risk characteristics follows a structured, logical approach that groups building characteristics according to their function. In this way, the methodology reflects the contribution of each characteristic to the overall building performance. This methodology relies on expert experience in wind engineering, damage observation from post-disaster surveys, and data from wind tunnel experiments. The ultimate goal is to develop a

©2019 AIR Worldwide

modification function that is applied to the base damage function—one that appropriately captures the impact of one or more selected building characteristics.

Weightings are used to combine the effects of secondary risk characteristics whose interaction is complex and not necessarily additive. These are introduced to evaluate features that modify the performance of the system. If we consider the roof system, age, pitch, and geometry modify the performance of the roof as a whole and therefore the weight should be used as a multiplier. The weights are dependent on wind speed and construction class, and are appropriately selected to reflect the importance of a feature at certain levels of a building's damage state.

Evaluating Building Performance

There are two primary metrics for evaluating the impact of a building or environmental feature on overall building performance. The first is a weighted value assigned to the various *options* for building or environmental features. The value for any given option of any given feature reflects the relative prevalence of use among the options and is independent of other features. That is, the value is designed such that the most commonly used option is assigned a value close to 1.0. The implication is that a building with this option is expected to perform very similarly to the average, or "typical," building represented by the base damage functions.

The value assigned for an option that is considered to be more vulnerable (less wind resistive) than the most commonly chosen one is greater than 1.0. That is, a building with this option will be more vulnerable than the average building. Similarly, the value assigned for an option that is considered to be less vulnerable (more wind resistive) than the most prevalent one will be less than 1.0. Such a building will be less vulnerable than the average building. If no information is available on the option, the default value is 1.00, which means that the base damage function is used without modification.

The second metric has two types. One type is used to develop simple weighted averages, which are used to evaluate the loss contribution of several features that together constitute a system, such as a roof. They are wind-speed dependent; that is, the contribution of each feature varies with wind speed. For example, a roof system may consist of three features: roof covering, roof deck, and roof attachment. The loss contribution to the roof system from these three features is expected to be different at different wind speeds. At low wind speeds, the roof covering drives the damage. As wind speeds increase, the roof deck becomes more vulnerable. In this case, roof deck failure will result in loss of roof covering regardless of the type (or option) of roof covering present. Therefore, as wind speed increases, the weight assigned to roof deck increases. In contrast, at higher wind speeds, the weight for roof covering decreases because it is already lost. The weights for the system as a whole add up to 1.0.

The second type of weighting combines the effects of features whose interaction is complex and not necessarily additive. These are introduced to evaluate features that modify the performance of the system. If we consider a roof system again, the roof age, roof pitch, and roof geometry modify the performance of the roof as a whole and therefore the weight should be used as a multiplier. The weights are dependent on wind speed and construction class, and are appropriately selected to reflect the importance of a feature at certain levels of building damage.

Example of Wind Speed Dependency

As noted above, the performance of secondary building characteristics is wind-speed dependent. This can be further explained by considering in detail a single feature, such as roof-wall anchorage. Roof-wall anchorage provides the means to establish a load path to transfer wind loads from the roof to the walls.

This anchorage can be provided through:

©2019 AIR Worldwide

- Hurricane straps
- Structural connections
- Nails
- Epoxy/adhesive
- Anchor bolts
- Gravity/friction

By selecting hurricane straps as one of the options for “roof wall anchorage” we can observe varying mitigation benefits in three different wind speed regimes.

- For lower wind speeds, the mitigation benefits (in terms of reduced damage) of hurricane straps are similar to any other roof-wall anchorage mechanism. Hence mitigation benefits are not high at these wind speeds.
- At higher wind speeds, hurricane straps are very effective in reducing damage. At these wind speeds, the presence of straps is most important. Hence mitigation benefits are high.
- At very high wind speeds, the effectiveness of hurricane straps in reducing the damage decreases. Hence, mitigation benefits are low.

Because of its inherent weakness, there are no mitigation benefits for “epoxy/adhesive” as an option for “roof wall anchorage.” In fact, “penalties” are applied and the size of the penalty is wind speed dependent.

- At low wind speeds, the effectiveness of “epoxy/adhesive” is similar to other roof-wall anchorage mechanisms. Hence we do not see any large penalties being exacted in this wind speed domain.
- At higher wind speeds, the choice of a weak roof-wall anchorage has a significant impact on damage. Hence we see high penalty being exacted.
- At very high wind speeds, most roof-wall anchorage mechanisms are ineffective. Thus the penalty for choosing a weak one is small.

The above examples illustrate how different wind speeds impact the accrual or non-accrual of mitigation benefits for a particular feature, as illustrated in Figure 14.

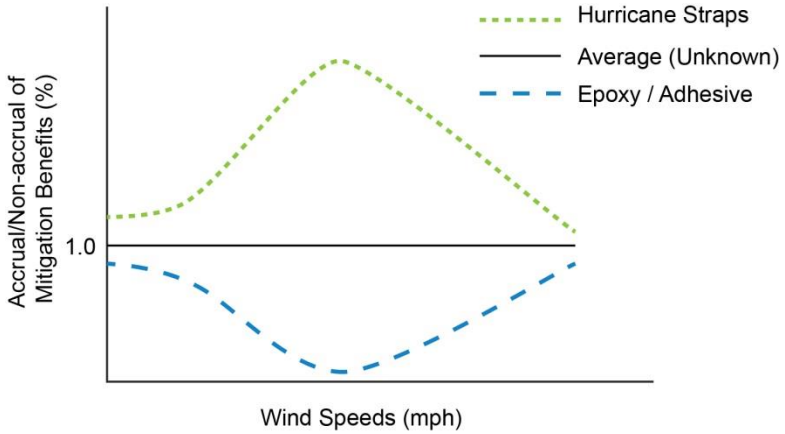

Figure 14. Mitigation Benefits of Various Roof-Wall Anchorage Options

©2019 AIR Worldwide

Sample Mitigation Curves

Failure of windows during a hurricane is often due to the impact of flying debris or to the exceedance of the window's pressure capacity. Window failure is a breach of the building envelope and allows wind and water to enter the building. Even if there is no structural damage to the building, this intrusion of water would cause damage to contents and building interior finishes, which can lead to substantial losses. Protecting the windows is critical in reducing the potential damage to a building. One mitigation option is the installation of engineered storm shutters.

As can be seen in Figure 15, the percentage reduction in damage achieved by the installation of engineered storm shutters is wind speed dependent. At lower and high wind speeds the percentage of reduction in damage is comparable to that of any other equivalent window protection mechanism. Hence we do not see any higher order percentage reduction of damage at lower and higher wind speeds. The effectiveness of engineered storm shutters is greatest in the middle range of wind speeds, where shutters have the greatest marginal impact on damage reduction.

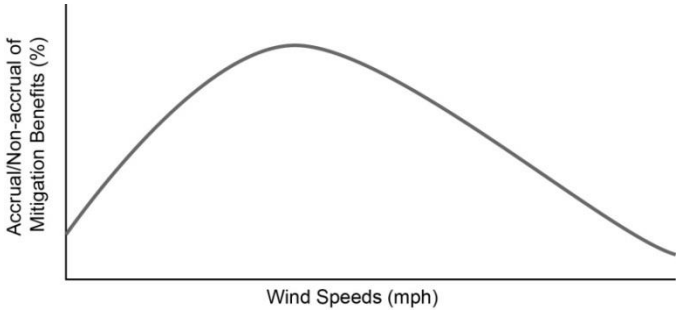

Figure 15. Modification Function for Engineered Storm Shutters

Damage to the roof covering can also result in significant water damage to the interior of the building and contents. A sample modification curve for a slate roof covering is provided in Figure 16.

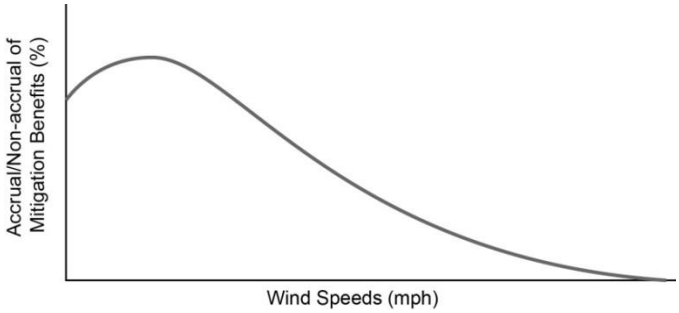

Figure 16. Modification Function for Slate Roofing

Spatial and Temporal Dependency of the Marginal Impact of Secondary Risk Characteristics

For a given construction type, occupancy class, and height, the AIR Hurricane Model for the U.S. defines a typical building in terms of default secondary risk characteristics, for each location and year built, to estimate its vulnerability. Thus the *marginal* impact on vulnerability of secondary risk characteristics is also dependent on the location of the structure and the year it was built. User input of secondary risk characteristics will overwrite the default characteristics, and a new vulnerability function is estimated depending on the user's input relative to default features. For

©2019 AIR Worldwide

example, an input of “engineered shutter” will provide no to minor reduction in vulnerability for a Miami home built after 2002, but will provide a large reduction in vulnerability for a Tallahassee home built before 1995. This coherent approach provides a framework that properly accounts for the overlap of the impact of different secondary features (e.g., year built and mitigation features) and avoids potential double counting of secondary features in the model. However, the overall vulnerability for a structure in Miami is likely to be lower than that of a building in Tallahassee. It is this marginal impact of secondary risk characteristics that will be different.

Validating the Impact of Secondary Risk Characteristics

The quality and level of detail of exposure and claims data has improved over time. Before the 2004 and 2005 hurricane seasons, most of the data was aggregated at the ZIP Code level with little to no information about individual building characteristics. Data from more recent storms indicates that most companies have started capturing exact addresses and primary building characteristics such as construction, occupancy, height, and year-built. Many clients have also captured detailed building characteristics such as roof covering type, type of opening protection, and roof sheathing connection, etc. AIR has analyzed this data to validate the impact of individual characteristics and characteristics in combinations. Figure 17 compares modeled and observed mitigating impacts of key individual building characteristics, as well as of the combined characteristics in a single building (mitigated building).

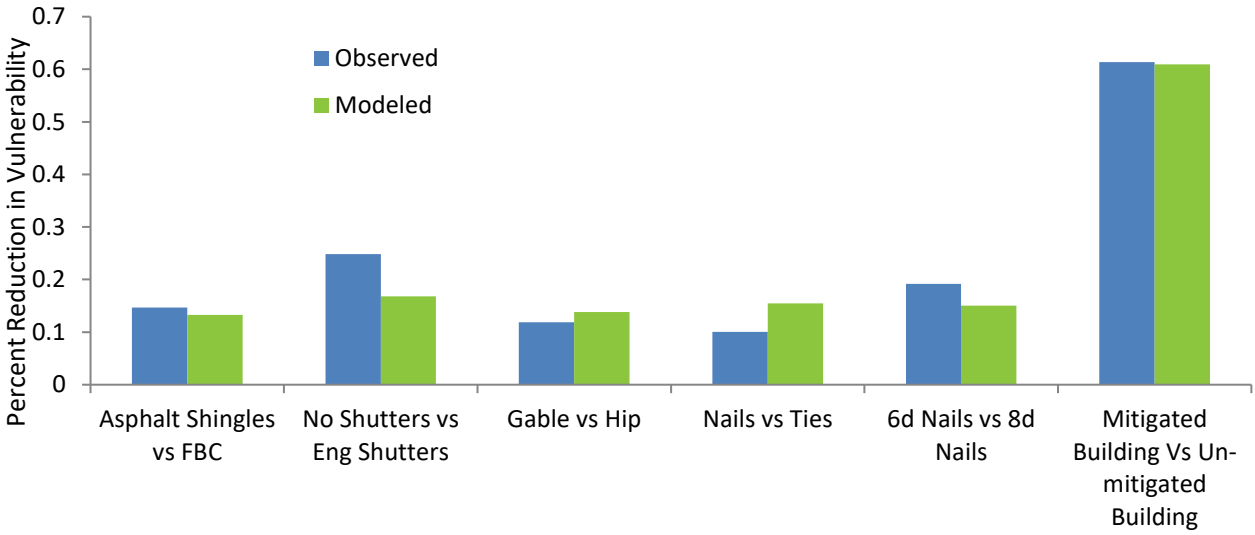

Figure 17. Validation of the Impact of Secondary Risk Characteristics, Alone and in Combination

Proper Use of the Secondary Risk Characteristic “Seal of Approval”

Even when building codes are mandatory, the level of engineering participation in the design and construction of a structure can vary regionally. In Florida, for example, a professional engineer typically performs an inspection and undertakes load calculations before engineering drawings are sealed. For many coastal counties in Texas, a professional engineer inspects the buildings, but design load calculations are not performed. For many other states, basic inspection is sufficient to meet the building code requirements.

In the AIR Hurricane Model for the U.S., the secondary risk characteristic “Seal of Approval” was developed to account for the differing effects the same class of mitigation features may have on

©2019 AIR Worldwide

the vulnerability of a structure. For example, the impact of a good roof-to-wall connection (e.g., strap) may be much higher for a home that received engineering attention during construction (e.g., design calculations were completed to ensure there are continuous horizontal and vertical load paths) than the impact on a home where such detailed engineered attention was not paid. The purpose of these features is not to turn a house with bad building characteristics into a good house with mitigation features, but to distinguish between the impact of a mitigation feature based on the level of engineering attention. Thus, the Seal of Approval will not change the vulnerability of a structure with otherwise poor building characteristics.

There are three options for the Seal of Approval:

> *Fully Engineered Structure*: The structure has been designed by a Professional Engineer. The Professional Engineer is required to seal the calculations and drawings by the local jurisdiction.
>
> *Partially Engineered Structure*: The structure has been inspected by a Professional Engineer and found "deemed-to-comply" with the respective Building Code. The local jurisdiction does not require the Professional Engineer to seal the calculations.
>
> *Minimally Engineered Structure*: The structure does not satisfy any of the conditions mentioned above.

Following are examples to illustrate the use of Seal of Approval in the model.

> *A Miami structure built in 2009:*
>
> The model assumes a well mitigated and Fully Engineered Structure for this location and year-built. Thus, using the Partially or Minimally Engineered options under Seal of Approval would increase the vulnerability of structures.
>
> *A Mississippi structure built in 1995:*
>
> The model does not assume a mitigated structure for this location and year-built. Thus, applying any option under Seal of Approval will not modify the vulnerability functions.
>
> *A Mississippi structure built in 1995 with user-selected secondary risk characteristics, such as high-wind rated roof covering, hurricane ties, and engineered shutters:*
>
> Since the user has selected secondary risk characteristics that will make the structure a mitigated structure, selecting the Partially Engineered or Fully Engineered options will further reduce the vulnerability of the structure.

Please note that when year-built is unknown, the Seal of Approval characteristic does not have an impact on the vulnerability.

Mitigation Credits for Construction to Florida Building Code 2001 (FBC 2001)

For buildings built to the minimum requirements of the FBC 2001, AIR has identified six unique building categories for Florida, as listed in Table 2, by taking into consideration the design wind speed, terrain exposure category, and the requirements of Wind-borne Debris Region (WBDR) and High Velocity Hurricane Zone (HVHZ).

Table 2. Building Categories According to FBC 2001

Building Category	Wind Speed*** (mph)	Exposure	WBDR**
1	<120	B	No

©2019 AIR Worldwide

Building Category	Wind Speed*** (mph)	Exposure	WBDR**
2	≥110	C	Yes
3	≥120	B	No
4	≥120	B	Yes
5	≥120	C	Yes
6	HVHZ*	C	Yes

*Broward and Miami-Dade counties

** In these areas, buildings can be designed for internal pressures instead of providing opening protections. In the model, explicit assumption about opening protection has not been made except for Region 6 where it is required to have the opening protection.

*** The wind speeds specified as per FBC 2001 are “nominal” or “basic” wind speeds as per allowable stress design (ASD)

Figure 18 shows the geographical locations of these building categories in Florida. The vulnerability functions for these six unique building categories were derived by selecting the relevant building features and options from the AIR individual risk module that meet the minimum requirements of FBC 2001. For example, AIR building category 6 is located in the HVHZ and is designed for a wind speed of 146 mph and Exposure C (Open country), as specified in FBC 2001. The code stipulates all openings be protected in the HVHZ.

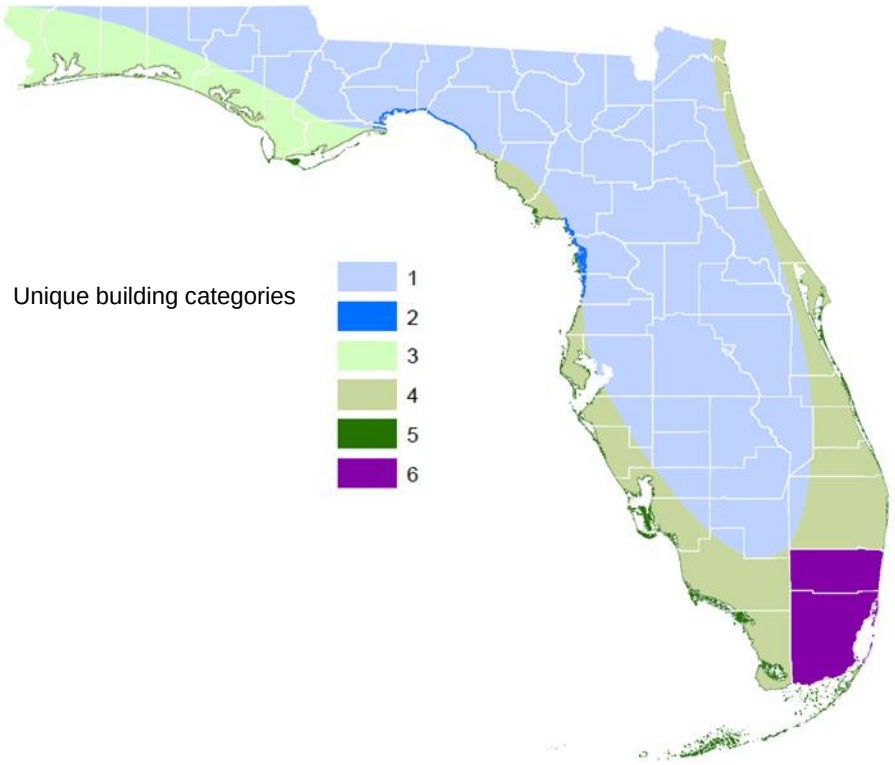

Figure 18. Buildings that Meet the Minimum Requirements of FBC 2001

©2019 AIR Worldwide

Table 3 illustrates the roof covering, roof covering attachment, roof deck, roof-deck attachment, roof anchorage, opening protection, and exterior door options selected for residential wood frame category 6 buildings to meet the minimum requirements of the Florida Building Code.

Table 3. Model Parameters for Building Category 6 According to the Minimum Requirements of FBC 2001

Parameter	Building 6
Wind Speed	146 mph
Exposure	C
WBDR	Yes
HVHZ	Yes
Roof Covering	FBC Equivalent
Roof Cover Attachment	Nails / Staples
Roof Deck	Plywood
Roof-Deck Attachment	8d@6"/6"
Roof Anchorage	Hurricane Straps
Window Protection	Engineered Shutters
Exterior Doors	Impact Resistant - Reinforced

Mitigation Credits for Construction to Florida Building Code 2010 (FBC 2010)

For buildings built to the minimum requirements of FBC 2010, AIR has identified eleven unique building categories for Florida, as listed in Table 4, by taking into consideration the design wind speed, terrain exposure category, and the requirements of WBDR and HVHZ.

Table 4. Building Categories According to FBC 2010

Building Category	Wind Speed*** (mph)	Exposure	WBDR**
1	115 ≤ < 130	B	No
2		C	No
3	130 ≤ < 140	B	No
4		C	No
5		B	Yes
6		C	Yes
7	140 ≤ < 155	B	Yes
8		C	Yes
9	≥ 155	B	Yes
10		C	Yes

©2019 AIR Worldwide

Building Category	Wind Speed*** (mph)	Exposure	WBDR**
11	HVHZ*	C	Yes

* Broward and Miami-Dade counties
** In the model, the opening protection is explicitly assumed for buildings in the WBDR.
*** The design wind speeds as per FBC 2010 are for risk Category II buildings and are “ultimate” wind speeds as per Load and Resistance Factor Design (LRFD)

Figure 19 shows the geographical locations of these building categories in Florida. The vulnerability functions for these eleven unique building categories were derived by selecting the relevant building features and options from the AIR individual risk module that meet the minimum requirements of the Florida Building Code 2010. For example, AIR building category 11 is located in the High Velocity Hurricane Zone (HVHZ) where the design wind speed is 170 mph and 175 mph in the Broward and Miami-Dade counties for risk Category II buildings, respectively, as specified in FBC 2010. In addition, Exposure C (Open country) is assumed in HVHZ. The code stipulates all openings be protected in High Velocity Hurricane Zone.

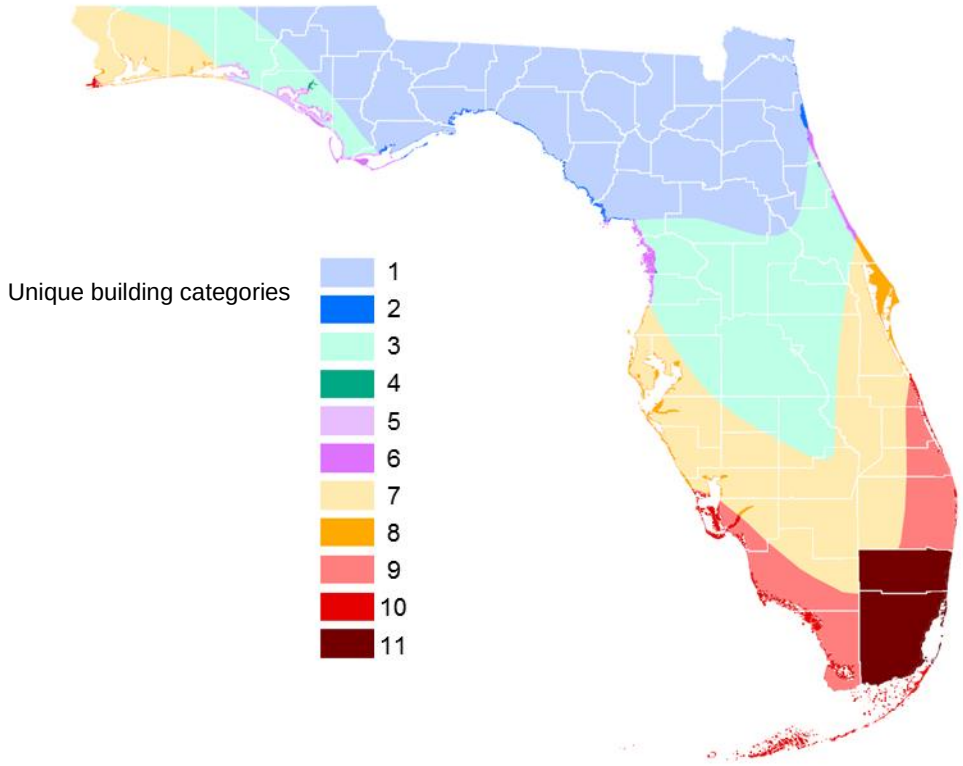

Figure 19. Buildings that Meet the Minimum Requirements of the Florida Building Code 2010

Table 5 illustrates the roof covering, roof covering attachment, roof deck, roof-deck attachment, roof anchorage, building foundation connection, opening protection, door, wall attached structures, and mechanical system options selected for residential wood frame category 11 buildings to meet the minimum requirements of the Florida Building Code 2010.

©2019 AIR Worldwide

Table 5 . Model Parameters for Building Category 11 According to the Minimum Requirements of FBC 2010

Parameter	Building 11
Wind Speed	170 or 175 mph
Exposure	C
WBDR	Yes
HVHZ	Yes
Roof Covering	FBC Equivalent
Roof Cover Attachment	Screws
Roof Deck	Plywood
Roof-Deck Attachment	Structurally Connected
Roof Anchorage	Hurricane Straps
Foundation Connection	Hurricane Straps
Window Protection	Engineered Shutters
Exterior Doors	Impact Resistant - Reinforced
Wall Attached Structures	None
Roof Attached Structures	Secondary Water Resistance - Yes

Evaluating Wind Loss Mitigation Credits with the Touchstone Location Detail Record

On June 6, 2002, the Florida Department of Insurance issued an Informational Memorandum **(**0470M) which outlined provisions of the Florida Statute Section 627.0629(1). The new statute requires that rate filings received by the Florida Department of Insurance on or after June 1, 2002, include credits for “fixtures or construction techniques demonstrated to reduce the amount of loss in a windstorm”. The statute further requires all insurers to make a rate filing which includes actuarially reasonable differentials by February 28, 2003.

This document provides guidance to companies who wish to use Touchstone for evaluating these wind mitigation credits. According to the statute, the following 6 areas must be considered:

- Roof strength
- Roof covering performance
- Roof-to-wall strength
- Wall-to-floor-to-foundation strength
- Opening protection
- Window, door, and skylight strength

©2019 AIR Worldwide

The Information Memorandum states that other construction techniques have also been demonstrated to influence loss and thus should also be considered:

- Roof shape
- Wall Construction
- Opening Protection for non-glazed openings (e.g., doors)
- Gable End Bracing for roof shapes other than hip

Touchstone Location Detail Record

The location detail record contains several building and environmental features that influence loss from windstorms. Table 6 shows the features of particular relevance to the Florida Statute.

Note that some features can be used to address more than one area of interest. For example, while roof geometry is a separate category, it also influences roof strength.

Table 6. Building Features Relevant to the Florida Statute

Mitigation Category	Touchstone Location Detail Field
Enhanced Roof Strength	Roof Deck Roof Deck Attachment Roof Covering Roof Covering Attachment Roof Geometry Roof Pitch Year Roof Built
Opening Protection	Window Protection
Opening Protection for Non-glazed Openings	Exterior Doors Wall Attached Structures
Roof Covering Performance	Roof Covering Roof Covering Attachment
Roof Shape	Roof Geometry
Roof to Wall Strength	Roof Anchorage Wall Type Wall Siding
Wall Construction	Wall Type Wall Siding
Wall to Floor to Foundation Strength	Foundation Connection
Window, Door, Skylight Strength	Glass Type Exterior Doors Wall Attached Structures

Developing Mitigation Credits

In 2001, the Florida Department of Community Affairs (DCA) commissioned a study to estimate the loss reduction potential of different wind resistive building features. Loss cost relativities were

©2019 AIR Worldwide

presented for a set of primary rating factors, with various options for each factor. The Florida Department of Insurance recognizes the “public domain” DCA study as one basis for deriving credits, but notes that insurers may rely upon other studies.

AIR has developed loss modification factors for a similar range of building features. Touchstone users may use these factors to develop rating credits in a similar manner as presented in the public domain study. It is important to note that the AIR and DCA studies were developed independently, and as a result have differences in methodology, features, and conclusions. While there is no direct mapping of the rating tables used in the DCA study to the AIR secondary characteristics, AIR has developed a list of characteristics that provide a similar range of relativities. The DCA features and closest AIR selections are shown in Table 7.

Table 7. DCA Features and Corresponding AIR Secondary Characteristics

DCA Feature	Similar AIR Category and Selections
Opening Protection None Basic Hurricane	Window Protection None Non-Engineered Shutters Engineered Shutters
Roof Cover Non FBC Equivalent FBC Equivalent	Roof Covering + Roof Covering Attachment Asphalt Shingles + Nails FBC Equivalent+Nails
Roof Deck Attachment A B C	Roof Deck + Roof Deck Attachment Plywood + 6d nails @ 6”/12” Plywood + 8d nails @ 6”/12” Plywood + 8d nails @ 6”/6”
Roof Shape Hip Other	Roof Geometry Hip Gable End without Bracing
Roof Wall Connection Toe Nails Clips Single Wraps Double Wraps	Roof Anchorage Nails/Screws Clips Hurricane Ties
Secondary Water Resistance	Secondary Water Resistance
No Secondary Water Resistance	No Secondary Water Resistance

The AIR study made use of the same 31 points used to define locations in the public domain study. The analysis showed that loss relativities did not vary significantly by location. The resulting AIR wind loss mitigation relativities are therefore presented as the mean of the relativities across all locations, and take into account locations in each of the wind speed and terrain exposure combinations implemented in the Florida Building Code.

About AIR Worldwide Corporation

AIR Worldwide (AIR) provides risk modeling solutions that make individuals, businesses, and society more resilient to extreme events. In 1987, AIR Worldwide founded the catastrophe modeling industry and today models the risk from natural catastrophes, terrorism, pandemics, casualty catastrophes, and cyber attacks, globally. Insurance, reinsurance, financial, corporate, and government clients rely on AIR's advanced science, software, and consulting services for catastrophe risk management, insurance-linked securities, site-specific engineering analyses, and agricultural risk management. AIR Worldwide, a Verisk (Nasdaq:VRSK) business, is headquartered in Boston with additional offices in North America, Europe, and Asia. For more information, please visit www.air-worldwide.com.

Model Evaluation by Water Lyons, CCM

MEMORANDUM

TO: E.W. Blanch Company

FROM: Walter A. Lyons, CCM

DATE: 21 April 1986

RE: Critique: Hurricane Simulation Model, Mainframe Version; Technical Documentation (March 1986) performed by Walter A. Lyons, Ph.D., CCM and Kenneth G. Bauer, Ph.D., R*SCAN Corporation, 511 Eleventh Avenue South, Minneapolis, MN 55415.

PURPOSE: The purpose of this memorandum is to critique and evaluate the above referenced document prepared by InSoft, Inc., of Hartford, Connecticut, in support of a Monte Carlo simulation of the impact of hurricane generated insured property losses due to wind and storm surges along the Gulf and Atlantic coastlines. A similar approach is being followed for assessing tornado damage impacts.

AUTHORIZATION:

The authorization to proceed was contained in a letter dated 10 January 1986 from Michael G. Wacek, Vice President, E.W. Blanch Company, Minneapolis, Minnesota.

SCOPE OF WORK:

R*SCAN Corporation and its principle scientists (Dr. Lyons and Dr. Bauer) were charged with the following tasks as per the above referenced letter and as clarified by subsequent meetings and conversations.

1. To acquire and inspect additional relevant meteorological literature pertaining to the problem under study.

2. Locate sources of additional meteorological data, information, and equations relevant to the various elements of a Monte Carlo simulation program for studying the maximum potential annual insured property losses due inflicted by hurricanes and tornadoes in the continental United States.

3. Review each of the meteorological elements and assumptions of InSoft, Inc.'s hurricane and tornado damage simulation models as to their completeness, and to the appropriate interpretation and use of the meteorological variables and equations therein.

4. Suggest additional information approaches which may be relevant to the study underway.

INTERACTIONS:

Three meetings were held with members of the E.W. Blanch team. The preliminary meeting in December, 1985, discussed the basic concepts concerned with developing a wind storm damage assessment model for use in reinsurance applica-

tions. Two extended meetings with M.G. Wacek and Karen Clark, developer of the model's software, were held in January and March 1986. Final revised equations used in the hurricane assessment portion of the modeling work were received by R*SCAN on 20 April 1986. A review was made of all materials prepared by InSoft, Inc., as well as the materials that served as their primary references, especially National Weather Service studies by Schwerdt, Ho, and Watkins (1979), and Ho, Schwerdt, and Goodyear (1975).

VISITS: In support of our investigations, the following site visitations were made to discuss various aspects of InSoft's model with scientific personnel.

1. January 1986. Dr. Lyons visited personnel of the National Hurricane Center and NOAA's Hurricane Research Division, both of Miami, Florida. Various relevant matters were discussed with Dr. Gill Clark, Dr. Charlie Newman, Dr. Peter Black, and Dr. Neil Frank, Director of the National Hurricane Center. Research on the various topics implicit in InSoft's modeling methodology were analyzed. The existance of a major parallel study at the University of Western Ontario was uncovered.

2. March 1986. Dr. Bauer visited personnel of the National Weather Service's National Severe Storms Forecast Center in Kansas City, Missouri. Various aspects of tornado climatologies were discussed with senior personnel including Dr. Preston Leftwich and Dr. Joseph Schaeffer of the NSSFC staff.

THE HURRICANE MODEL:

It must be recognized that it is essentially impossible to simulate mathematically in detail all aspects of even a single hurricane, much less properly recreate, using statistical approximations, detailed characteristics of a large number of such storms. The InSoft model represents a compilation of statistical parameterizations, which introduce a certain degree of non-conformance to reality into the simulated storm. On the other hand, many of these impacts are inconsequential and in many cases are self-cancelling in their impact. It should be noted that in current meteorological forecasting practice, physical models are executed every 12 hours by the National Meteorological Center for large regions of the northern hemisphere. These models also include a variety of physical and statistical parameterizations that represent only crude approximations of actual atmospheric processes. On the whole, the ensemble statistical measures of model accuracy prove to be surprisingly robust and show a high degree of skill. While there are no present verification statistics available for the InSoft hurricane model, the degree of parameterization and statistical approximation employed does not appear either to be inconsistent with the current state-of-the-art or to introduce any obvious major errors into the simulated wind field and storm surge. It must also be understood that it would be virtually impossible to find a meteorological specialist who would agree with the exact specifications used in each one of the model's components and submodules. However, the same could be said of almost any statistical or meteorological model. The ultimate question is whether or not the final results would appear plausible and consistent with observations.

R*SCAN scientists reviewed InSoft's parameterizations for model variables including annual hurricane frequency, distribution of landfall frequencies,

distribution of minimum central pressure at landfall, the radius of maximum wind, storm forward motion and direction at the point of landfall, and the equation used to generate the maximum gradient wind surrounding the central eye of the storm. In addition, they also reviewed terms to simulate the well known asymmetry of the hurricane wind field and the filling of the storm over land. It was suggested that corrections be made for the approximation to the air density term in the gradient wind equation which resulted in up to a 5% error in peak wind speeds near the center of the storm. This correction has subsequently been made. We note that the minimum lower bound for central pressure for landfall of Atlantic hurricanes is set at 26.10" which is 0.25" lower than the extreme recorded value to date. The term describing the forward speed of the storm as a function of latitude was corrected from the original version to give it a more realistic fit to observed storm speeds along the mid- and North Atlantic coasts, i.e., the hurricane of 1938 which was moving at approximately 60 kts at landfall. The factor used for the adjustment of wind speed for surface friction is plausible. It must be noted that the .45 rough terrain factor must be interpreted with some caution. While as an areal average wind speed it may be a reasonable approximation, it must be remembered that in larger urban areas the channeling of winds through urban canyons could produce locally higher, not lower, wind speeds. These micrometeorological effects may be important in the study of damage to highrise structures. Also, the gust factor in extremely rough (urban) terrain could be quite dissimlar to those values found over smoother land areas.

It should also be noted that in the calculation of peak storm surge height, local ocean bottom topography can play a significant role in the elevation of sea level at any given point such as a small harbor or estuary. These terms are not accounted for in this model, but it is uncertain whether or not this represents a significant omission with respect to the impact on damage generation.

A minor correction to the 20 March 1986 document is suggested. On page 12, in the discussion of the overland filling equations, a term V_h is introduced to represent the wind speed at the "eye" of the storm. The wind speed at the center of the storm is by definition, zero (0). A different phraseology is preferred. It is presumed the that V_h represents the speed at the radius of maximum wind.

TORNADO SIMULATION:

Far less material was available to evaluate InSoft's approach to the modeling of the potential damaging impact of tornado systems in the United States. One major misconception was discovered in the original formulations, i.e., that the Fujita F-Damage Scale provided by the National Severe Storms Forecast Center on the tornado data tapes represented the values that could be applied along the entire length of a tornado's path. In fact this is generally construed to represent the maximum F-scale reached by a given tornado.

A review of the meteorological data and equations presented as the basis for the InSoft, Inc. Tornado Simulation Model found them to be a knowledgeable representation of the field, based on the materials contained in the InSoft literature list. Additional sources of information made available should, however, be carefully considered before closing the design of the Tornado Simulation Model. In particular, the NOAA Technical Memorandum by Schaefer, Kelly, and Abbey (1985) presents summarized tornado characteristics and suggests a minimum

assumption tornado hazard probability model based on a thorough analysis of available data. Access to data analysis and modeling programs is available at reasonable cost through the National Severe Storms Forecast Center. Use of a distribution of F level damage based on the maximum F level as given by Schaefer, et al. (1985) on page 24 would seem to be more realistic than assuming the wind speed remains constant throughout the duration and path of the storm as described in the final paragraph of the 10 December 1985 InSoft, Inc. letter to Dr. Lyons.

A discussion of tornado outbreaks or "families" is presented in Galway's 1977 journal article. The updated tornado data tape may permit an expansion of the work of Galway for inclusion in the InSoft, Inc. tornado model.

REFERENCE MATERIALS DELIVERED:

Additional sources of information were investigated by R*SCAN Corporation and provided to InSoft, Inc. for their use in further formulating its model. These references include the following articles:

Plus, selected preprints from the American Meteorological Society 14th Conference on Severe Local Storms.

RECOMMENDATIONS:

Upon review of the materials provided by InSoft, Inc., discussions within R*SCAN Corporation and scientists at government laboratories, and upon review of additional literature over and above that provided by E.W. Blanch, the following recommendations and suggestions are provided for consideration by E.W. Blanch Company.

1. In order to demonstrate the model performance it is recommended that actual simulations of major recent hurricanes such as Camille, Alicia, Frederic, and Gloria be performed to compare predicted versus observed insured damage losses.

2. Another approach somewhat different from a Monte Carlo simulation techniques might also shed some light on the maximum credable damage impact from a severe hurricane might be to use the model to simulate the impact of a Class 5 hurricane on major urban centers such as Houston, New Orleans, Miami, and New York City. Even in a large number of years of simulation, it is possible that a Class 5 hurricane may not impact on the most damage prone areas. Given that the likelihood of such an event is definately non-zero, then this would provide at least some upward bounded estimate of the plauseable maximum impact of a severe hurricane.

3. It was recommended to correct the erroneous density term in the approximation to the gradient wind equation used within the model. (Already implemented)

4. An interesting exercise might be to obtain, at the beginning of each hurricane season, the forecast prepared by Professor William Gray of Colorado State University as to the number of anticipated Atlantic hurricanes that will impact the United States coastline. Given the predicted number of storms, and using the otherwise statistically generated landfall distributions, a prediction of the possible ranges of hurricane generated damage for the upcoming year could be prepared. This might have potential educational as well as promotional value.

5. Similarly, it would appear entirely feasible that before the actual landfall of an impending storm, model parameters such as minimum central pressure, radius of maximum wind, storm speed and direction, etc., could be introduced into the model to generate a forecast of the insured damages anticipated from each storm. If this approach is successful it would help gain credability for the statistical approach employed as well as provide a promotional vehicle for E.W. Blanch.

6. With regards to tornado simulations, it is suggested that most of the effort be expended on the simulation of the impact of moderate to intense tornadoes, i.e., those rated as Class F2 or greater. The overall impact of these storms is by far and away the most significant. As has been noted, they have significantly different geographical and temporal distributions as the more numerous F0 and F1 classification storms.

7. It is strongly recommended that the tornado data tapes updated through the 1985 season be acquired. Major tornado outbreaks occurring in Ohio and Pennsylvania in 1985 and in North and South Carolina in 1984 will have significant statistical impact upon the distribution of F4 and F5 tornadoes in the densely populated eastern United States.

8. If one wishes to simulate the maximum possible credible tornado event, the Tri-state tornado of March, 1925 may provide a model.

This storm, which still rates today as the single deadliest individual tornado, just missed a large number of major metropolitan areas. The same storm placed on a track that would include urban centers such as Kansas City, St. Louis, or Indianapolis would likely provide a reasonable upper bound for the impact of a major tornado in the United States.

9. If InSoft, Inc. has not already done so, it is recommended that contact be made with the research meteorologist studying storm tornado wind damage assessments at Texas Tech University in Lubock, Texas (Professors Minor and McDonald).

CONCLUSION:

The various assumptions, both explicit and implicit, of InSoft's modeling approach have been evaluated by R*SCAN Corporation. Not every aspect of the parameterizations and statistical distributions could be studied in great detail simply due to time and resource limitations. It is felt, however, that a scientifically defenseable and realistically complete approximation of these major storm systems has been achieved. However, as in all modeling efforts, it is important to realize that the model output should be validated against actual observations. In this case, model results against actual damaging storm systems would provide model validation, and allow for any necessary calibration to be employed. The users should have a reasonable confidence as to whether or not there is a systematic underprediction or overprediction resulting from the model assumptions employed.

On the whole, it is felt that the proposed models are scientifically well based and reflect an understanding of the current state-of-the-art of atmospheric sciences.

2019 Vulnerability Standards

External Reviewer Comments

AIR's 2019 Vulnerability Standard submission has been reviewed. The following sections provide reviewer comments for each standard and disclosure.

V-1 Derivation of Building Vulnerability Functions

A. Development of the building hurricane vulnerability functions shall be based on at least one of the following: (1) insurance claims data, (2) laboratory or field testing, (3) rational structural analysis, and (4) post-event site investigations. Any development of the building hurricane vulnerability functions based on rational structural analysis, post-event site investigations, and laboratory or field testing shall be supported by historical data.

> The vulnerability functions in the AIR Hurricane Model for the U.S. were developed using research results published in the engineering literature, post-hurricane damage investigations conducted by experts in wind engineering, and insurance loss data. AIR has used results of structural analysis performed by wind engineering experts, post-hurricane field investigation results, updated engineering literature, computational simulations, and analysis of loss data to update and improve the vulnerability standards since their initial development.

B. The derivation of the building hurricane vulnerability functions and their associated uncertainties shall be theoretically sound and consistent with fundamental engineering principles.

> Vulnerability functions and their associated uncertainties within the AIR Hurricane Model for the U.S. were derived by experts in wind and structural engineering from published literature and have been validated by results of damage surveys and historical claims data. To deal with the uncertainties, the damage functions include probability distributions around the mean damage ratio that varies as a function of wind speed. The vulnerability functions have been peer reviewed, both internally and externally. This overall approach to development of the vulnerability functions is theoretically sound and consistent with fundamental engineering principles.

C. Residential building stock classification shall be representative of Florida construction for personal and commercial residential buildings.

> The building stock classification set has been derived from census, tax assessor, engineering surveys, construction reports, and other sources. From these data, building stock classifications representative of Florida construction have been chosen.

D. Building height/number of stories, primary construction material, year of construction, location, building code, and other construction characteristics, as applicable, shall be used in the derivation and application of building hurricane vulnerability functions.

> The AIR Hurricane Model for the U.S. includes 34 vulnerability functions based on primary construction material (e.g., wood frame, masonry veneer – detailed in Disclosure V.1.6) and number

of stories for single family residential (i.e., traditional construction and manufactured housing) and commercial residential (i.e., apartment buildings and condominiums). For single family residences, which are most commonly just one or two story, there is no variation of vulnerability functions with height. Building height is categorized for commercial residential structures based on primary construction material, with a maximum of three height categories. Building code and enforcement are accounted for regionally and temporally through application of vulnerability adjustment modifiers. Year-built categories include pre-1995, 1995-2001, 2002-2011, and post-2011. Other construction characteristics are addressed through the Individual Risk Module.

E. Hurricane vulnerability functions shall be separately derived for commercial residential building structures, personal residential building structures, manufactured homes, and appurtenant structures.

The AIR Hurricane Model for the U.S. includes separate vulnerability functions for commercial residential and personal residential primary structures, manufactured homes, and appurtenant structures. The model includes separately-derived vulnerability functions based on coverage type (e.g., appurtenant structures are considered under separate coverage), and primary and secondary characteristics, which include occupancy (e.g., personal residential and commercial residential are separate occupancies) and construction class (e.g., manufactured homes are in a separate construction class), among other characteristics.

F. The minimum windspeed that generates damage shall be consistent with fundamental engineering principles.

The AIR Hurricane Model for the U.S. uses a sustained (one-minute) average wind speed of 40 mph as the minimum threshold for wind damage. This lower bound has been verified through engineering research, damage surveys, and historical claims data.

G. Building hurricane vulnerability functions shall include damage as attributable to windspeed and wind pressure, water infiltration, and missile impact associated with hurricanes. Building hurricane vulnerability functions shall not include explicit damage to the building due to flood (including storm surge and wave action).

The AIR vulnerability functions explicitly account for damage as a function of wind speed (and by extension, wind pressure). Damage due to water infiltration and windborne missile impacts are handled implicitly, having been calibrated and validated using insurance claims data. Storm surge, flooding, and wave action are not explicitly included in the AIR Hurricane Model for the U.S.

Disclosures

1. Describe any modifications to the building vulnerability component in the hurricane model since the previously accepted hurricane model.

The building vulnerability component of the AIR Hurricane Model for the U.S. addresses four key updates. Three of these updates address temporal factors to make the model relevant to 2020, namely: pre-computed factors that adjust base wind structural vulnerability when year built information is unavailable; vulnerability adjustments that account for structural aging and building technology changes, along with aging and deterioration of roofs; and defaulting “roof year built” secondary risk feature to a new roof for buildings less than ten years old. These modifications are reasonable and reflect the changing characteristics of the residential building stock.

2. Provide a flow chart documenting the process by which the building hurricane vulnerability functions are derived and implemented.

Figure 28 of AIR's V-1 response shows the process by which the vulnerability functions were derived and implemented. The flowchart shows how published research, engineering expertise, and results of damage surveys are combined to create the vulnerability functions, which are calibrated and validated by insurance industry claims and loss data. Within the validation process, modeled and actual damage ratios are associated with wind speeds and compared to determine if adjustments are needed in the vulnerability functions. The process is repeated until modeled and actual damage ratios are comparable.

3. Describe the nature and extent of actual insurance claims data used to develop the building hurricane vulnerability functions. Describe in detail what is included, such as, number of policies, number of insurers, dates of hurricane loss, amount of hurricane loss, and amount of dollar exposure, separated into personal residential, commercial residential, and manufactured homes.

AIR has made extensive use of insurance claims data in validation of the model, from multiple companies and multiple storms since 1983. In addition to data specific to Florida, loss data from other areas has also been evaluated, including Hurricanes Ike, Irene, Isaac, and Sandy. Loss data have been used in both model development and model validation and come from company clients and Verisk's Property and Claims Services. New data are analyzed as they become available and relevant findings are incorporated once data validation is complete. AIR has received detailed data covering more than $2.5 trillion of personal, $6 billion of manufactured homes, and $75 billion of commercial residential exposure.

4. Describe any new insurance claims datasets collected since the previously-accepted hurricane model.

Since the previously-accepted hurricane model, AIR has obtained industry insured loss estimates from Verisk's Property and Claims Services for 2017 and 2018 hurricanes impacting Florida based on business line: personal, commercial, automobile. These data are generally at the state level or, for more significant events such as 2017 Hurricane Irma and 2018 Hurricane Michael, at the county level.

5. Describe the assumptions, data (including insurance claims data), methods, and processes used for the development of the building hurricane vulnerability functions.

The vulnerability functions are based on engineering analysis, post-event damage surveys, expert consultation, and analysis of claims and industry loss data. In addition to the academic and industry background of AIR's engineering team, assessment of peer-reviewed literature and input from external reviewers ensure reasonable results.

6. Summarize post-event site investigations, including the sources, and provide a brief description of the resulting use of these data in the development or validation of building hurricane vulnerability functions.

AIR has fielded post-hurricane investigations for significant hurricanes that make landfall in the U.S. since Hugo in 1989, including several more recent hurricanes in 2012, 2015, 2017, and 2018. In addition, AIR has surveyed damage from major storms outside the mainland U.S., including 2017 Hurricane Maria in Puerto Rico and 2019 Hurricane Dorian in the Bahamas. These site inspections have served to enhance the in-house expertise on wind damage vulnerabilities and to help identify and confirm performance issues of different types of construction.

Generalizations regarding the performance of buildings in past events have found that “engineered” structures perform better that their “non-engineered” counterparts (both commercial and residential), the importance of year built on residential vulnerability, wind effects on non-structural elements, damage regimes for residential buildings based on windspeed, the improved wind resistance of masonry full-height exterior walls compared with wood-framed construction, and the importance of time effects for building vulnerability. This information obtained from post-event site investigations has been incorporated into the development and validation of the vulnerability model.

7. Describe the categories of the different building hurricane vulnerability functions. Specifically, include descriptions of the building types and characteristics, building height, number of stories, regions within the state of Florida, year of construction, and occupancy types for which a unique building hurricane vulnerability function is used. Provide the total number of building hurricane vulnerability functions available for use in the hurricane model for personal and commercial residential classifications.

Vulnerability functions are included in the AIR Hurricane Model for the U.S. for construction types that address the majority of personal and commercial residential construction in Florida, classified by occupancy, construction type, and height, year of construction, and gross area. These functions are further modified for secondary risk characteristics including region, siting considerations, construction details, year of construction, and building codes. Vulnerability functions for commercial residential occupancies are developed considering building height, as such structures vary more widely than the typical 1-2 stories for single family residences.

8. Describe the process by which local construction practices and statewide and county building code adoption and enforcement are considered in the development of the building hurricane vulnerability functions.

To account for variations in building code provisions, AIR has identified 11 unique building categories based on design wind speed, terrain exposure category, and code requirements of Windborne Debris Regions (WBDR) and High Velocity Hurricane Zones (HVHZ). Vulnerability functions have been developed for these building categories, representative of buildings built to the minimum requirements of FBC 2001 and 2010. Variations in local construction practices, building code adoption, code enforcement, and their effects on projected losses are handled as secondary risk characteristics in the Individual Risk Module, where detailed information can be input by the model user.

9. Describe the relationship between building structure and appurtenant structure hurricane vulnerability functions and their consistency with insurance claims data.

The building structure and appurtenant structure vulnerability functions are calculated independently. Damage to an appurtenant structure is calculated separately from the primary structure based on the hazard and known characteristics of the appurtenant structure. Appurtenant structure vulnerability functions were developed through analysis of claims data, published research, and damage surveys when possible.

10. Describe the assumptions, data (including insurance claims data), methods, and processes used to develop building vulnerability functions when:

1. ***residential construction types are unknown, or***
2. ***one or more primary building hurricane characteristics are unknown, or***
3. ***one or more secondary characteristics are known, or***
4. ***building input characteristics are conflicting.***

Data provided by client companies, the census, and tax assessors are used to identify typical residential construction types within a region. Using these data, vulnerability functions for unknown residential construction types are developed through a weighted average of residential building vulnerability curves based on the prevalence of building construction types in that region. When primary building hurricane characteristics are unknown, a weighted average vulnerability function developed from the known characteristics is used to approximate the vulnerability function. The use of weighted average functions is a sound practice and is combined with proprietary and publicly available exposure data. This weighting does not apply to manufactured homes.

When secondary characteristics are known, this information is input into the Individual Risk Module, which modifies the vulnerability functions. Given the definitions of building input characteristics, it is reasonable to assume that conflicting data do not arise.

11. Identify the one-minute average sustained windspeed and the windspeed reference height at which the hurricane model begins to estimate damage.

The AIR Hurricane Model for the U.S. uses a sustained (one-minute) average wind speed of 40 mph as the minimum threshold for wind damage, measured at a reference height of 10 m, which is the standard for measurement and reporting of wind speeds. This lower bound wind speed is consistent with damage surveys and published literature.

12. Describe how the duration of windspeeds at a particular location over the life of a hurricane is considered.

The AIR Hurricane Model for the U.S. includes the effects of hurricane duration using a stepwise procedure. For each given location, for the first period during the storm when the sustained winds exceed 40 mph, the damage occurring during this period is estimated, and the remaining undamaged portion of the exposure is determined. For each successive period where the winds exceed 40 mph, the same procedure is followed, and the remaining undamaged portion is subjected to damage in each time interval. In this manner, longer duration storms having the same maximum speed as shorter duration storms will show accumulation of additional damage, as has been reflected in damage surveys. The AIR hurricane model team members presented a well-received paper on duration effects and how to model them at the 11th America's Conference on Wind Engineering in Puerto Rico in June 2009.

13. Describe how the hurricane model addresses wind-borne missile impact damage and water infiltration.

The AIR Hurricane Model for the U.S. implicitly addresses wind borne missile impact damage and water infiltration to the extent that these damage types are included in historic insurance claims data. Additionally, the debris environment can be described through additional secondary characteristics (if known), selected by the user. The ability of the structures to resist water infiltration can also be described through mitigation techniques as a secondary characteristic through the Individual Risk Module.

14. Provide a completed Form V-1, One Hypothetical Event. Provide a link to the location of the form here.

See the section entitled Form V-1, One Hypothetical Event for reviewer comments.

V-2 Derivation of Contents Hurricane Vulnerability Functions

A. Development of the contents hurricane vulnerability functions shall be based on at least one of the following: (1) insurance claims data, (2) tests, (3) rational engineering analysis, and (4) post-event site investigations. Any development of the contents hurricane vulnerability functions based on rational engineering analysis, post-event site investigations, and tests shall be supported by historical data.

The vulnerability functions for contents in the AIR Hurricane Model for the U.S. were developed using research results published in the engineering and insurance literature, post-event damage investigations conducted by experts in wind engineering and damage, and analysis of available loss data. AIR has used updated research literature, computational simulations, and analysis of loss data to update and improve the contents vulnerability functions since their initial development.

B. The relationship between the hurricane model building and contents hurricane vulnerability functions shall be consistent with, and supported by, the relationship observed in historical data.

Based on a review of a scatterplot provided by AIR showing modeled and historical content and building losses, the relationship between modeled and historical building and contents loss is reasonable, with less scatter in the simulated loss.

Disclosures

1. Describe any modifications to the contents vulnerability component in the hurricane model since the previously accepted hurricane model.

No changes are reported for the AIR Hurricane Model for the U.S. contents vulnerability components related to wind hazards since the previously accepted model.

2. Provide a flow chart documenting the process by which the contents hurricane vulnerability functions are derived and implemented.

Derivation and implementation of the contents vulnerability functions follow the same process used in the derivation and implementation of the building vulnerability functions, which is sound.

3. Describe the assumptions, data (including insurance claims data), methods, and processes used to develop and validate the contents hurricane vulnerability functions.

Vulnerability functions for contents coverage are calculated as a function of building damage. Contents vulnerability functions are treated differently for personal and commercial residential structures, as the relationship between building and contents losses are different for these categories of buildings. AIR uses the same process to validate contents loss functions as is used for building vulnerability validation. Validation considers content vulnerability functions at levels ranging from aggregate industry level losses to evaluation of claims data for individual policies, considering losses before and after application of policy terms.

4. Provide the total number of contents hurricane vulnerability functions. Describe whether different contents hurricane vulnerability functions are used for personal residential, commercial residential, manufactured homes, unit location for condo owners and apartment renters, and various building classes.

There are distinct underlying contents vulnerability functions for personal and commercial residential buildings, as described in V-2.3. Given the two basic contents vulnerability functions for these two

occupancies, there is a unique contents vulnerability function for each building construction/occupancy type.

5. Describe the relationship between building structure and contents hurricane vulnerability functions.

The vulnerability functions for contents coverage are calculated as a function of mean building damage. The contents damage functions have been developed from claims data, published studies, and expert engineering judgment. Values for contents losses are calculated separately from building damage.

V-3 Derivation of Time Element Hurricane Vulnerability Functions

A. Development of the time element hurricane vulnerability functions shall be based on at least one of the following: (1) insurance claims data, (2) tests, (3) rational engineering analysis, and (4) post-event site investigations. Any development of the time element hurricane vulnerability functions based on rational engineering analysis, post-event site investigations, and tests shall be supported by historical data.

Time element vulnerability functions in the AIR Hurricane Model for the U.S. were developed using research results published in the engineering and insurance literature, post-event damage investigations conducted by experts in wind engineering and damage, and analysis of available loss data. AIR has used updated research literature, computational simulations and analyses, and analysis of loss data to update and improve the time element functions since their initial development.

B. The relationship between the hurricane model building and time element hurricane vulnerability functions shall be consistent with, and supported by, the relationship observed in historical data.

Based on a review of a scatterplot provided by AIR showing modeled and historical time element and building losses, the relationship between modeled and historical building and time element vulnerability functions is reasonable.

C. Time element hurricane vulnerability function derivations shall consider the estimated time required to repair or replace the property.

The time element vulnerability is based on the mean building damage, the estimated time to repair or replace the property, and the estimated cost of time element coverage. The estimated time required to repair or replace the property implicitly considers damage to the surrounding infrastructure and costs to temporarily relocate displaced occupants.

D. Time element hurricane vulnerability functions used by the hurricane model shall include time element hurricane losses associated with wind, missile impact and flood (including hurricane storm surge) and damage to the infrastructure caused by a hurricane.

The time element vulnerability functions include time element hurricane losses associated with wind, missile impact, flood, and storm surge damage to infrastructure to the extent that these data are reflected in the model validation data (i.e., damage surveys and insurance claims data).

Disclosures

1. Describe any modifications to the time element vulnerability component in the hurricane model since the previously-accepted hurricane model.

No changes are reported to the time element vulnerability component since the previously accepted hurricane model.

2. Provide a flowchart documenting the process by which the time element hurricane vulnerability functions are derived and implemented.

Derivation and implementation of the time element vulnerability functions follow the same process used in the derivation and implementation of the building vulnerability functions, which is sound.

3. Describe the assumptions, data, methods, and processes used to develop and validate the time element hurricane vulnerability functions.

The time element vulnerability is based on the mean building damage, the estimated time to repair or replace the property, and the estimated cost of time element coverage. For low wind speeds, building damage is low and time element vulnerability is also low; however, at high wind speeds with significant damage, time element vulnerability can be significant, which has been seen in recent events.

AIR uses the same process to validate time element loss functions as is used for building vulnerability validation. Validation considers time element vulnerability functions at levels ranging from aggregate industry level losses to evaluation of claims data for individual policies, considering losses before and after application of policy terms.

4. Describe how time element hurricane vulnerability functions take into consideration the damage (including damage due to flood (including hurricane storm surge), and wind) to local and regional infrastructure.

Time element vulnerability functions implicitly take into consideration local and regional infrastructure damage to the extent they are reflected in the historical insurance loss data used in model development, calibration, validation. The AIR Hurricane Model for the U.S. does not explicitly estimate losses from precipitation induced flood damage.

5. Describe the relationship between building structure and time element hurricane vulnerability functions.

The time element vulnerability is based on the mean building damage and the estimated time to repair or reconstruct the damaged building. The relationships between building loss of use and building damage have been established based on published construction data and engineering judgment. Validation data implicitly include infrastructure damage and the costs for temporary relocation and other needs in the time element vulnerability functions.

V-4 Hurricane Mitigation Measures and Secondary Characteristics

A. Modeling of hurricane mitigation measures to improve a building's hurricane wind resistance, the corresponding effects on hurricane vulnerability, and their associated uncertainties shall be theoretically sound and consistent with fundamental engineering principles. These measures shall include fixtures or construction techniques that affect the performance of the building and the damage to contents and shall consider:

- ***Roof strength***
- ***Roof covering performance***
- ***Roof-to-wall strength***
- ***Wall-to-floor-to-foundation strength***
- ***Opening protection***
- ***Window, door, and skylight strength***

AIR's Individual Risk Module incorporates features to allow consideration of the identified wind mitigation measures.

B. The modeling organization shall justify all hurricane mitigation measures and secondary characteristics considered by the hurricane model.

The Individual Risk Module allows for consideration of a range of mitigation measures and secondary risk characteristics through modification functions, which vary with wind speed. Features have been selected based on research and damage surveys and include structural and non-structural elements, along with building condition and environmental features. This approach to modeling the effects of mitigation measures is theoretically sound and consistent with fundamental engineering principles.

C. Application of hurricane mitigation measures that affect the performance of the building and the damage to contents shall be justified as to the impact on reducing damage whether done individually or in combination.

The effects of mitigation measures within the AIR Hurricane Model for the U.S. have been validated from previous hurricane damage reports, engineering judgment, and available loss data. The percentage change in losses associated with the individual mitigation measures demonstrates their relative effectiveness in various wind speed regimes. Combinations of mitigation measures provide additional protection compared to single measures, but the benefits are appropriately not always equal to the linear sum of benefits from the individual measures. For example, a building having storm shutters that protect impact resistant windows would have a mitigation credit of less than the sum of these two individual measures, as there is some redundancy in the protection offered by shutters and impact glass.

D. Treatment of individual and combined secondary characteristics that affect the performance of the building and the damage to contents shall be justified.

The AIR Individual Risk Module incorporates information about secondary characteristics through a structured, engineering-based framework that can be applied for one or more secondary characteristics using modification functions, which vary with wind speed. These modification functions have been developed using engineering principles and building performance observations and validated with historical insurance loss data. Content vulnerability functions are calculated as a function of the building vulnerability functions and would therefore reflect the inclusion of secondary characteristics.

Disclosures

1. Describe any modifications to mitigation measures in the model since the previously accepted model.

Since the previously accepted hurricane model, a temporal modification has been made to make the model relevant to 2020: defaulting of the "roof year built" secondary risk feature to a new roof for

buildings less than ten years old has been updated. Additionally, roof age assignment has been updated to classify buildings built 10 to 20 years ago as having an “average” roof year built when the roof year built is unknown.

2. Describe the software used to calculate the impact of hurricane mitigation measures and secondary characteristics, its identification, and current version. Describe whether or not such software has been modified since the previously-accepted hurricane model.

The Individual Risk Module is used to calculate the impact of hurricane mitigation measures and secondary characteristics. This module has been updated as described in Disclosure V-4.1 for roof year built.

3. Provide a completed Form V-2, Hurricane Mitigation Measures and Secondary Characteristics, Range of Changes in Damage. Provide a link to the location of the form here.

See comments provided in the section entitled Form V-2, Hurricane Mitigation Measures and Secondary Characteristics, Range of Changes in Damage.

4. Provide a description of the hurricane mitigation measures and secondary characteristics used by the hurricane model, whether or not they are listed in Form V-2, Hurricane Mitigation Measures and Secondary Characteristics, Range of Changes in Damage.

The mitigation measures listed in Table 14 of AIR’s V-3 response are comprehensive and reasonable reflections of factors that affect building performance in windstorms.

5. Describe how hurricane mitigation measures and secondary characteristics are implemented in the hurricane model. Identify any assumptions.

Mitigation measures and secondary characteristics are implemented through AIR’s Individual Risk Module using modification functions. Each modification function captures the changes in building vulnerability from the computed base vulnerability function associated with a particular mitigation measure as a function of wind speed. This modification is reflective of the effectiveness of the mitigation feature(s) in reducing damage under different intensity winds. Mitigation effects are determined based on structural engineering expertise and building damage observations. Mitigation modification functions that represent a combination of building features are applied to the base vulnerability functions to provide vulnerabilities for mitigated buildings. The way in which mitigation modifies the base vulnerability function is based on various ‘rates and weights.’ Rates account for the prevalence of use among the various mitigation options. Weights account for situations where more than one mitigation option is present. The AIR Individual Risk Module assigns two types of weights to each mitigation measure, one for when multiple mitigation features are related to performance of the same system (e.g., the roof system), and the other for combinations of the effects of features that are more complex. The values of the weighting functions are dependent on wind speed. AIR’s system for handling mitigation options is robust and capable of handling mitigation of single elements, whole building systems (e.g., roof systems—comprised of roof coverings, decking, framing, and attachment of decking and framing), and combinations of multiple elements and systems.

6. Describe how the effects of multiple hurricane mitigation measures and secondary characteristics are combined in the hurricane model and the process used to ensure that multiple hurricane mitigation measures and secondary characteristics are correctly combined.

Within the AIR Hurricane Model for the U.S., the effects of mitigation measures and secondary characteristics are not simply calculated as the linear sum of individual measures, but consider the

combination of effects with multiple mitigation measures and secondary characteristics across varying wind speeds, described in V-3.4. This is a sound theoretical approach, and validation is performed to ensure that modeled mitigation factors are representative of historical insurance loss data. The system of weighting functions appears well designed and able to account for the wide range of possible interactions of various mitigation measures.

7. Describe how building and contents damage are affected by performance of hurricane mitigation measures and secondary characteristics. Identify any assumptions.

The performance of mitigation measures and secondary characteristics is explicitly accounted for in the estimation of building damage through the development of modified building vulnerability functions as described in V-3.4. The performance of mitigation measures is accounted for in the calculation of contents damage, as contents damage is calculated as a function of building damage.

8. Describe how hurricane mitigation measures and secondary characteristics affect the uncertainty of the vulnerability. Identify any assumptions.

AIR vulnerability functions are characterized by a mean damage ratio as a function of hazard intensity with an associated probability distribution around the mean damage ratio. Inclusion of mitigation measures and secondary characteristics alters the mean damage ratio and in turn the associated probability distribution. This practice is sound and consistent with engineering principles.

9. Provide a completed Form V-3, Hurricane Mitigation Measures and Secondary Characteristics, Mean Damage Ratios and Hurricane Loss Costs (Trade Secret Item), if not considered as Trade Secret. Provide a link to the location of the form here.

See comments provided in the section entitled Form V-3, Hurricane Mitigation Measures and Secondary Characteristics, Mean Damage Ratios and Hurricane Loss Costs.

10. Provide a completed Form V-4, Differences in Hurricane Mitigation Measures and Secondary Characteristics. Provide a link to the location of the form here.

See comments provided in the section entitled Form V-4, Differences in Hurricane Mitigation Measures and Secondary Characteristics.

11. Provide a completed Form V-5, Differences in Hurricane Mitigation Measures and Secondary Characteristics, Mean Damage Ratios and Hurricane Loss Costs (Trade Secret Item), if not considered as Trade Secret.

See comments provided in the section entitled Form V-5, Differences in Hurricane Mitigation Measures and Secondary Characteristics, Mean Damage Ratios and Hurricane Loss Costs.

Form V-1: One Hypothetical Event

A. Windspeeds for 96 ZIP Codes and sample personal and commercial residential exposure data are provided in the file named "FormV1Input19.xlsx." The windspeeds and ZIP Codes represent a hypothetical hurricane track. Model the sample personal and commercial residential exposure data provided in the file against these windspeeds at the specified ZIP Codes, and provide the building and contents damage ratios and time element loss ratios summarized by windspeed (mph) and construction type.

The windspeeds provided are one-minute sustained 10-meter windspeeds. The sample personal and commercial residential exposure data provided consists of four structures (one of each construction type – wood frame, masonry, manufactured home, and concrete) individually placed at the population centroid of each of the ZIP Codes provided. Each ZIP Code is subjected to a specific windspeed.

For completing Part A, Estimated Damage for each individual windspeed range is the sum of ground up hurricane loss to all structures in the ZIP Codes subjected to that individual windspeed range, excluding demand surge and flood (including hurricane storm surge). Subject Exposure is all exposures in the ZIP Codes subjected to that individual windspeed range.

For completing Part B, Estimated Damage is the sum of the ground up hurricane loss to all structures of a specific type (wood frame, masonry, manufactured home, or concrete) in all of the windspeed ranges, excluding demand surge and flood (including hurricane storm surge). Subject Exposure is all exposures of that specific construction type in all of the ZIP Codes.

One reference structure for each of the construction types shall be placed at the population centroid of the ZIP Codes. Do not include appurtenant structure, contents, or time element coverages in the building damage ratios. Do not include building, appurtenant structure, or time element coverages in the contents damage ratios. Do not include building, appurtenant structure, or contents coverages in the time element loss ratios.

Based on experience, the AIR Hurricane Model for the U.S. results presented in Parts A and B appear reasonable in absolute magnitude and in the ranges and trends. In the Part B submission, the relative performance of the construction types appears reasonable. Manufactured homes have a long and well documented history of poor performance compared to site-built homes (although the performance of newer manufactured homes has been improving). This expected result is demonstrated. Similarly, concrete buildings historically outperform wood framed or masonry buildings, which is reflected in Part B results. Masonry buildings are shown to slightly outperform wood framed buildings, which is also expected due to the increased strength of the exterior walls. The modeled event used by AIR for the current Form V-1 submission are based on wind speeds of 1-hour duration. It is expected that losses from a 1-hour duration event would be significantly less than would be observed following a typical hurricane duration. At the request of the review, AIR produced additional modeling data to confirm the magnitudes of damage by wind speed and construction type (Parts A and B) corresponding to a longer duration event. These results are in line with reviewer experience of building performance.

B. Confirm that the structures used in completing the form are identical to those in the above table for the reference structures. If additional assumptions are necessary to complete this form (for example, regarding structural characteristics, duration, or surface roughness), provide the reasons why the assumptions were necessary as well as a detailed description of how they were included.

The AIR Hurricane Model for the U.S. requires a sustained (one-minute) wind speed time profile to calculate damage ratios. For the purposes of Form V-1, AIR has assumed a hypothetical event of 1-hour duration, which is a different assumption than in previous submissions. Additionally, the AIR Hurricane Model for the U.S. considers actual terrain surface roughness to calculate the wind speeds used in Form V-1.

C. Provide separate plots of the Estimated Damage/Subject Exposure (y-axis) versus Windspeed (x-axis) for the Building, Contents, and Time element data in Part A.

Plotted Estimated Damage/Subject Exposure plots are reasonable for the reference structures and wind speeds of 1-hour duration.

D. Include Form V-1, One Hypothetical Event, in a submission appendix.
Form V-1 was reviewed in Excel format without truncation.

Form V-2: Hurricane Mitigation Measures and Secondary Characteristics, Range of Changes in Damage

A. Provide the change in the zero deductible personal residential reference building damage ratio (not hurricane loss cost) for each individual hurricane mitigation measure and secondary characteristic listed in Form V-2, Hurricane Mitigation Measures and Secondary Characteristics, Range of Changes in Damage, as well as for the combination of the four hurricane mitigation measures and secondary characteristics provided for the Mitigated Frame Building and the Mitigated Masonry Building below.

The relative effectiveness of different hurricane mitigation measures with wind speed is presented in the tables of AIR's Form V-2 response. Form V-2 reports relative changes in mean damage ratio, which can be difficult to interpret. Therefore, Form V-3 for the current and previous submission were reviewed and were found to reflect relatively minor changes in mean damage ratios, which is reasonable.

Combined with review of Form V-3, the values provided in Form V-2 appear reasonable and appropriate in magnitude and variation with wind speed, based on reviewer experience. The general magnitudes and trends in change in damage for the fully mitigated frame and masonry buildings appear reasonable and in line with reviewer experiences and expectations. For example, damage for the mitigated frame and masonry buildings is approximately half as much as the reference structure for sustained wind speeds of 85-110 mph. This very significant improvement in performance is expected, as the selected mitigation options address several of the most common design and construction deficiencies that prevent buildings from performing satisfactorily at speeds near design code values.

B. If additional assumptions are necessary to complete this form (for example, regarding duration or surface roughness), provide the rationale for the assumptions as well as a detailed description of how they are included.

The AIR Hurricane Model for the U.S. requires a sustained (one-minute) wind speed time profile to calculate damage ratios. Therefore, a set of events were created to approximate the wind speeds at the specified locations. Duration effects were not accounted for in the response to V-2.

C. Provide this form in Excel format without truncation. The file name shall include the abbreviated name of the modeling organization, the hurricane standards year, and the form name. Also include Form V-2, Hurricane Mitigation Measures and Secondary Characteristics, Range of Changes in Damage, in a submission appendix.

Excel versions of Forms V-2 and V-3 without truncation were reviewed.

Form V-3: Hurricane Mitigation Measures and Secondary Characteristics, Mean Damage Ratios and Hurricane Loss Costs (Trade Secret Item)

A. Provide the mean damage ratio (without including any insurance considerations) to the reference building for each individual hurricane mitigation measure and secondary characteristic listed in Form V-3, Hurricane Mitigation Measures and Secondary Characteristics, Mean Damage Ratios and Hurricane Loss Costs (Trade Secret item) as well as the percent damage for the combination of the four hurricane mitigation measures and secondary characteristics provided for the Mitigated Frame Building and the Mitigated Masonry Building below.

The table in the Form V-3 form response provided to the reviewer contains mean damage ratios for the reference and mitigated frame and masonry structures, as well as for structures with single mitigation options. The general magnitudes and trends of the mean damage ratio variation with wind speed for these structures and mitigation options appear reasonable and in line with reviewer experiences and expectations. As discussed in the review of Form V-2, mean damage ratios for the mitigated wood frame structure are on the order of half as much as the reference structure for sustained wind speeds of 85-110 mph, which is an expected result, as the selected mitigation options address several of the most common design and construction deficiencies that prevent buildings from performing satisfactorily at speeds near design code values. At sustained winds of 160 mph, the mitigation measures still provide significant improvement in mean damage ratio, but relatively less improvement compared to the reference structure. This again is an expected result, as wind loads and debris associated with these higher wind speeds are well beyond those anticipated in the design code, exposing many more potential failure modes than the common ones addressed by the four selected mitigation options.

B. Provide the zero deductible personal residential hurricane loss cost rounded to three decimal places, for the reference building and for each individual hurricane mitigation measure and secondary characteristic listed in Form V-3, Hurricane Mitigation Measures and Secondary Characteristics, Mean Damage Ratios and Hurricane Loss Costs (Trade Secret item) as well as the hurricane loss cost for the combination of the four hurricane mitigation measures and secondary characteristics provided for the Mitigated Frame Building and the Mitigated Masonry Building below.

The loss cost reflects the mean damage ratio presented in V-3 applied to the structure value. As detailed in Form V-3.A, the mean damage ratios are in line with expected results, yielding appropriate loss cost.

C. If additional assumptions are necessary to complete this Form (for example, regarding duration or surface roughness), provide the rationale for the assumptions as well as a detailed description of how they are included.

The AIR Hurricane Model for the U.S. requires a sustained (one-minute) wind speed time profile to calculate damage ratios. Duration effects were not accounted for in the response to V-3.

D. Provide a graphical representation of the hurricane vulnerability curves for the reference building and the fully mitigated building.

Graphical representation of the mean damage data presented in V-3 accurately represent the tabular values provided, and are appropriate, as discussed in the review of Form V-3.A.

E. If not considered as Trade Secret, provide this form in Excel format without truncation. The file name shall include the abbreviated name of the modeling organization, the hurricane standards

year, and the form name. Also include Form V-3, Hurricane Mitigation Measures and Secondary Characteristics, Mean Damage Ratios and Hurricane Loss Costs (Trade Secret Item), in a submission appendix.

An Excel version of Form V-3 without truncation was reviewed.

Form V-4: Differences in Hurricane Mitigation Measures and Secondary Characteristics

A. Provide the differences between the values reported in Form V-2, Hurricane Mitigation Measures and Secondary Characteristics, Range of Changes in Damage, relative to the equivalent data compiled from the previously-accepted hurricane model.

Values provided by AIR in Form V-4 were visually reviewed and found to agree with differences from the previous Form V-2 submission.

B. Provide a list and describe any assumptions made to complete this form.

Please see the review of Form V-2.B.

C. Provide a summary description of the differences.

The differences are not substantive, with the maximum difference of 1.5%.

D. Provide this form in Excel format without truncation. The file name shall include the abbreviated name of the modeling organization, the hurricane standards year, and the form name. Also include Form V-4, Differences in Hurricane Mitigation Measures and Secondary Characteristics, in a submission appendix.

The reviewer was provided a copy of Form V-4 in Excel format without truncation.

Form V-5: Differences in Hurricane Mitigation Measures and Secondary Characteristics, Mean Damage Ratios and Hurricane Loss Costs (Trade Secret Item)

A. Provide the differences between the values reported in Form V-3, Hurricane Mitigation Measures and Secondary Characteristics, Mean Damage Ratios and Hurricane Loss Costs (Trade Secret Item), relative to the equivalent data compiled from the previously-accepted hurricane model.

Values provided by AIR in Form V-5 have been confirmed through reviewer calculation of Form V-3 data for the previous and current submission.

B. Provide a list and describe any assumptions made to complete this form.

Please see the review for Form V-3.C.

C. Provide a summary description of the differences.

Moderate differences are shown on Form V-5, most notably at 135 mph for both frame and masonry structures. Some variation in the mean damage ratios provided in Form V-3 is expected between submissions given continuous validation of the vulnerability model.

D. If not considered as Trade Secret, provide this form in Excel format. The file name shall include the abbreviated name of the modeling organization, the hurricane standards year, and the form name. Also include Form V-5, Differences in Hurricane Mitigation Measures and Secondary Characteristics, Mean Damage Ratios and Hurricane Loss Costs (Trade Secret Item), in a submission appendix.

The reviewer was provided a copy of Form V-5 in Excel format without truncation.

CONCLUSION

The Hurricane Standards Report of Activities as of November 1, 2019 by the Florida Commission on Hurricane Loss Projection Methodology has been reviewed. The information submitted by AIR Worldwide in response to this document has been reviewed in detail for each of the standards and disclosures. A summary of AIR's response and evaluation of the approach has been provided by the reviewer.

Based on this review, AIR's response appears thorough and complete. The vulnerability functions within the AIR Hurricane Model for the U.S. have been developed and validated through research reported in the insurance and wind and structural engineering literature, engineering analysis, post-storm field investigations by engineering experts, and historical insurance claims data. The AIR team has significant experience and expertise in this area and has actively presented results of its vulnerability research at national and international engineering conferences. The methodology used in development of the vulnerability functions is theoretically sound. Implementation of these vulnerability functions produces reasonable damage ratios in line with insurance loss data and reviewer expectations.

Carol Friedland, P.E., Ph.D., C.F.M.

Curriculum Vitae for Dr. Narges Pourghasemi

Narges Pourghasemi

Mobile: 949-300-5159 npghasemi@yahoo.com Lake Forest, CA 92609

Sr. Software Engineer / Software Consultant

A versatile and result-oriented Software Developer professional with expertise in System Analysis, Design, Development and Product Enhancement. Over 20 years of consistently proven success, designing and developing Software (full SDLC practice) for E-commerce, web applications, Distributive systems, GUI, animation and Embedded Systems.

Equally effective working alone or in teams; Excellent Customer-Interface skills; Distinguished academic and teaching experience. Proven ability to quickly grasp new challenges, master new technologies and achieve tangible results.

US Citizen.

Industries: Cloud, Enterprise Software, SaaS, Aerospace, Air travel, Flight Entertainment, Automative, Insurance, Financial, Entertainment, Natural Language Processing, Medical Devices, IT Audit and International enterprises.

Technical Proficiencies

Languages / Frameworks	**Java, Spring WS, MVC, hibernate, EJB/ Java Beans, JPA, Deltaspike, Java Servlets, Java Swing, JavaScript, C/C++, JSP, ASP, HTML, XML/XSL, CSS, Ajax, Python, PERL, PHP, Velocity, X11/Motif, OpenGL, LISP, FORTRAN, Assembly, Groovy, UNIX Shell Scripts (ksh, csh, bsh, FreeBSD), awk, sed, MySQL, JDBC, Oracle 11, SQL, DB2, iBatis/MyBatis, ETL.**
Operating Environments	Java EE Platform, UNIX, Linux, LAMP, Timesys Embedded Linux, ARM, AIX, HP-UX, Mac OS , X-Window, Xcode VMS, VOS, IRIX, SUN, IBM AS400/i-series, IBM RISC, MS Windows, GDS/CRS, Apache Tomcat, Websphere, Jboss 7, WildFly, Agile Scrum.
Communications	HTTP, X.25, MATIP, EDIFACT, FTP, TCP/IP and Sockets.
Tools/Utilities	IDE (Eclipse, Net Beans, JBoss Studio, MS Visual Studio, IntelliJ,Xcode); GUI Builders (Builder Xcessory, UIM/X); SCM(Rational ClearCase/ClearRequest, Visual SourceSafe, AccuRev, CVS, SVN, Maven); Debuggers (xde, dbx, gdb, xdb), AC3D, GIMP, PhotoShop CS4 SDK, vi, Emacs, WebEX, Visio, UML, VMware, SoapUI.

EXPERIENCE

IMIS Consulting Group, Arlington, VA 2014 – Present

Advisory Board Member & Sr. Consultant – Provide information and materials, and make recommendations on project structure, effective planning, policies and assortment of technology. Assisting on Data integration projects.

MERCURY TECHNOLOGY GROUP, Irvine, CA Feb 2015- Oct 2016

Senior Java EE Web Application Developer- Solutions– Design, development, testing and system application support for a new Web Portal application system in support of company's cloud services infrastructure and customer offerings. The portal system managed client service tickets using emails based on the Notify ticketing system that was maintained in an Oracle 11g. The system was integrated on Window/Linux environment platform. The middle tier business layer was SpringMVC based written in Java.
Environment: Java EE platform, Spring Web Services, MVC, hibernate, EJB/ Java Beans, JPA, SOAP, WSDL, RESTful, Apache Deltaspike, Tomcat, JBoss 7, WildFly, Oracle 11, SQL, Maven, SVN, Linux, Eclipse, SoapUI, SVN.

SOLERA HOLDINGS INC. (formerly DST), Lake Forest, CA 2011- Oct 2014

e-Commerce Application Developer (Java EE Web Services Developer) – Development, Enhancement, basic project management, and updating assortment of eCommerce Enterprise Web Applications for the Aftermarket Automotive Industry, using Java, IBM DB2/SQL, SOAP/REST. Integration of in-house and 3rd party web services, application, Catalog providers and Electronic Data, i.e, EPICOR (formerly Activant), MOTOR FleetCross, ADP Dealer Services, and ACDelco OE. GUI design, and software technical documentation.
Environment: Java, Java EE platform,Web Services, Servlets, SOAP, WSDL, RESTful, AXIS, Apache Tomcat, WebSphere, JAXB, JDBC, IBM DB2, SQL, MyBatis (iBATIS), IBM iSeries(AS400), XML/XSD, Myeclipse, SoapUI, SVN, FTP, HTTP, Linux, PHP.

Independent Software Consultant **2004 – Present**

APPLIED INSURANCE RESEARCH (AIR WORLDWIDE CO.), Boston, MA (2006-2008, 2010, 2012, 2016, 2018)

IT Auditor (Independent Consultant)– Peer Review of the software and the development process of the Hurricane Insurance Model written in C++ & Fortran. The intent of review is to ensure that not only the application development process follows the current industry-standard software engineering practices, but also it complies with the software standards and requirements established by the Florida Commission on Hurricane Loss Projection Methodology as well. Interviewed with all involved IT and modeling group's manager or proxy to discuss and review the process. Provided recommendations for improvements in implementation and documentations, which some of them incorporated into Florida Hurricane Commissions Standards .

THE WALT DISNEY TELEVISION ANIMATION – Glendale, CA (2010)

Software Consultant- Implemented assortment of tools including: Writing a script in Python to execute commands on the specified hostname (remote shell) with some security measurements. Writing Photoshop plug-ins for formatting in different color space. Researched for Parallelism of Video encoding.
Environment: Mac OS 6, Window 7, MS Visual Studio, C/C++, Python, Shell scripts, Linux, Sockets, Photoshop CS4 SDK and plug-in.

TANDEM DIABETES CARE – San Diego, CA (2009-2010)

Software/Firmware Consultant - Developed scripts in Lisp to test embedded system medical devices. This tool used for Hardware testing using Emacs on Mac OS X; and the Firmware was written in C.

Freelance Software/Web Developer - Orange County, CA (2008-2009, 2011)

Design and Development of Websites and Marketing solutions for assortment of Professionals and Services, including Architectural Firm, Dental offices.

CHARLES RIVER ANALYTICS, INC. , Cambridge, MA (2006)

Designed and implemented a Graphical User Interface of an editor for the emulator data exploited in a Context-driven Infospace Configuration for Air Force Research Lab, using **Java Swing**, XML. Wrote the User Manual for this tool; and reformatted other tools documentations into the User Manuals. Research and Analysis of using B-Net for the application.

KAYAK, Concord, MA (2005)

Assisted in development of *Internet Travel Product,* for a travel meta-search company, using Java, J2EE/Tomcat/Struts, extensive HTTP Protocols, XML/DOM/SOAP/AXIS/WSDL, AJAX, Velocity, PHP, HTML, MySQL, CVS, Mac OS X.

TAXWARE, Salem, MA. (2004–2005)

Ported the Tax Management application from SUN Solaris to AIX and Linux platforms. Enhanced, optimized and fixed software defects of the application's front-end.
Environment: X/Motif, Builder Xcessory GUI builder, C on variety of Unix/Linux platforms.

IMS COMPANY, Brea, CA 2011

Sr. Software Engineer – Development of an application for Acceptance Testing Procedure, Performance Verification and Environmental Stress testing of Hardware parts used for a portable in-flight entertainment embedded device.
Environment: C++, Linux/ Ubuntu, SVN, ARM, VMware, Curses, Eclipse, UML, Timesys Embedded Linux, Agile.

LANGUAGE WEAVER, Los Angeles, CA 2009

Sr. Software Developer in Test - Designed and Developed stress and performance tools for software testing and quality assurance including a multithread test tool for REST based application in Java and scripts in Perl, Groovy and Ruby.
Environment: J2EE, Java, Mod Perl, Ruby, Groovy, Linux, VM, SVN, Agile, SCRUM.

DIGITAL RIVER, Eden Prairie, MN /Aliso Viejo, CA 2008

Principal Software Engineer – Designed and Developed the web application User interface for a middle tier management service for complex business services in multi-data center, clustered environment, transparent remoting, service oriented architecture and plugins framework.
Environment: J2EE, Java, JavaScript, XHTML/CSS, AJAX, Tomcat, CVS.

TALEND, Costa Mesa, CA 2007

Technical Consultant – Combined pre-sale/post-sale and technical consultant for an open source data integration tool. Worked with the business developer teams to manage the technical sales cycle and with the customers and partners to bring the technical expertise. Presented more than 60 WebEx demonstration to the prospective customers.
Environment: Java, PERL, Eclipse RCP, MySql, XML, PHP, Tomcat, ETL, Data Integration, JasperSoft reporting tool.

SITA (formerly EQUANT Application Services), Burlington, MA. 1999-2003

Senior Software Engineer – Advance Travel Solutions- Contributed to various projects for a spectrum of clients in the provision of E-Commerce and On-Net application solutions with focus on global airline and travel. The EDI-Application Gateway is constructed around the industry standard seven-layer model for communication architectures.

Conducted the *Message Switch System* setup for a **$20M contract project** with *CCRA* (*Canada Customs and Revenue Agency)* to provide advanced passenger information on all passengers traveling on in-bound international flights to Canada. On time comple- tion of this work, with high degree of quality, and in the absence of an accountable engineer, helped contribute to a new $4M tar- get achievement for phase one (Message Switch) of the project.

Web application Development: Enhanced the SITA Flight Finder Web Applications for the AirOne (Italian Airline) reservation, for the Canada3000 Airline reservation and in-house utility applications, and for SITA Air Cargo Carriers. *Environment*: ASP, JSP, HTML CSS, **Java**, J2SE, Java Servlets, **MVC**, Java Beans, JavaScript , MySQL, JDBC, PERL.

Enhanced communication interface of the SITA Interline Through Check-In (ITCI) system, Air Faring and E-Ticketing Interfaces, to support EDIFACT interchange.

Improved the message exchange interfaces between Amadeus CRS and SITA host servers using the MATIP (Mapping of Airline Traffic over IP) protocol for Type A (Conversational, Host to Host) and Type B traffics.

Wrote utility programs to allow batch files to work under different operating systems after porting the base model and test suite from Stratus/VOS to UNIX;

Assisted for development of a Gateway system to be used to bridge the Canada3000 Tour Operator sales into SITA's Gabriel CRS (Computer Reservation Systems) for centralized inventory control.

Initiated porting, the complex source base which included the application and the operating environment, from RISC platform to SUN Solaris. Conformed the updated Software Environment and System Configuration;

Rapidly grasped knowledge of the application systems, core products and CRS interfaces, and the company proprietary software development and runtime environment, in a short period of time and was appointed to provide full time support to a major client, Carlson Wagonlit Travel. Served as a consultant; assisted in work estimate, enhancements, for American Express.

- Provided consultant services and developed constant enhancements to the APIs and CRS Gateways based on customer requests and CRS changes.
- Interfaced with Client staff to determine change/enhancement requirements.
- Coordinated all work and frequent releases. Provided written release notes; ensured on time releases.
- Maintained API documentation, and handled writing procedures for support of system and status reports.
- Worked on several projects concurrently and communicated with cross functional teams located in Atlanta and UK.

Environment: *Proprietary Software Environment, C based and Scripting Proprietary Languages*, C, NT 4.0, X.25, MATIP, TYPE A/B *messages*, TCP/IP, SUN Solaris, VOS/Stratus, PERL and MS Visual Studio, Source Safe.

U.F.A. INC., Woburn, MA. 1994 -1999

Senior Software Engineer – Involved in all phases of software development and GUI Design for simulation and modeling of an air traffic management system on a distributed system.

Responsible for Data Preparation component for the major client, DFS (Germany's Federal Aviation Administration). Involved in design and development/enhancement of graphical editors and support tools.

Created a library from scattered codes for the graphical display of radar geographical backgrounds. The creation of this library, subsequently used in the Situation Display and all Data Preparation applications, made code enhancement much easier.

Designed and developed tools for data extraction and conversion from large external data sources: Jeppesen Sanderson navigation database and ICAO FPL recorded Flight Plans database.

Designed and developed the Graphical User Interfaces (GUI) for Data Preparation utilities.

Evaluated and used the COTS GUI builder (UIM/X) for prototyping and development.

Designed and developed Radar Message Filter Editor, an X Window/GUI based tool, for the Raytheon Company.

Consulted in pre-sales activities, scheduling, time/cost estimation, and all Software and User specifications issues.

Environment: C, IBM RISC 6000, UNIX, X11/Motif, UIM/X, ClearCase, DSEE, TCP/IP, Sockets, SGI, SUN, Apollo.

EDUCATION

NORTHEASTERN UNIVERSITY- Boston, M.A. 2004-2005

Ph.D. Candidate (ABD) in Computer System Engineering, Industrial Eng. Dept.
Area of Concentration: Software Engineering, User Interface Design/Human factor (User adaptive interfaces).

GEORGE WASHINGTON UNIVERSITY - Washington, D.C.

Professional Degree in Engineering; Computer Science/Artificial intelligence; minor in Medical Engineering.

UNIVERSITY OF NEW HAMPSHIRE - Durham, N.H., M.S. in Computer Science ***(Artificial intelligence)***

UNIVERSITY OF TEHRAN, B.S. in Computer Science and Mathematics.

Microsoft Windows Embedded Certificate: **Developing Embedded Solutions for Windows XP Embedded.**

Model Evaluation by Dr. Narges Pourghasemi

Model Evaluation by Narges Pourghasemi

A Peer Review of AIR Hurricane Model for the U.S. (M521 version 1.0.0) as implemented in Touchstone® 2020

Touchstone® is a product of AIR Worldwide

Narges Pourghasemi
Independent Information Technology Auditor

September 22-25, 2020

Overview

This document summarizes the peer review I conducted in September of 2020 for AIR Worldwide's implementation of their AIR Hurricane Model for the U.S. within the Touchstone® software. The intent of the review is to ensure that not only the application development process follows the current industry-standard software engineering practices but also it complies with the software standards and requirements established by the Florida Commission on Hurricane Loss Projection Methodology as well. This year the audit performed via Microsoft Teams Meeting for presentations, interviewing staff and reviewing the documents remotely due to Covid-19 pandemics restrictions.

Findings of the Peer Review

This review is based on AIR's Touchstone® 2020 version and Model 521 version 1.0.0. This year audit sessions were under different circumstances than previous years and carried out by audio/visual screen share only. There was no access to any documents or code, yet the substantiated documents were presented trough MS Teams Meeting.

The focus of the audit process was mostly on new enhancements. This year, AIR changed the internal model number from M21 to M521 and restarted the version from 1.0.0. The reason for this Model replacement was that to separate the code base of the model to be used for ratemaking in the state of Florida. The original M21 includes precipitation-induced flood as of Touchstone 8.0, and cannot be used for ratemaking in the state of Florida. M521 continues as before with the wind and storm-surge perils.

The findings are grouped according to the seven computer standards established by the Florida Commission on Hurricane Loss Projection Methodology as of November 2019. The following personnel or proxies from the following groups were presented during the audit: documentation, Product Management, Research & Modeling, Meteorology, Software Development Group, Database group, Release Engineer, Quality Assurance and IT/Security personnel, and Client Services Group, who demonstrated their knowledge of the pertinent subjects. In this interview process, the requirements for all sections C1-C7 of the Florida Commission's standards were discussed and reviewed with the personnel of each group, via Microsoft Teams Meeting.

Standard CI-1: Hurricane Model Documentation

AIR Worldwide maintains a central document management and repository *AIRPort*, which is a SharePoint repository, for both internal user and external clients documentations. *Microsoft Teams* provides an interface for accessing the SharePoint repository.

The documentations are created separately from the source code and stored in the repository which easily accessible online by all staff and designate external client users. During entire audit process, AIR personnel were utilizing this *AIRPort* repository to present the software documentations, requirements, software design and implementation, test procedures and plans, code guidelines and IT policy. All the documents for all section or group consist of a revision history, author, approver, and table of contents.

Software and model-related documentation is generated and maintained by each of these groups: Software Documentation, Research, Modeling, Software Development, Client Services, Security, Support and Quality Assurance. It is verified that each of these groups reviewed and signed out the documentation for each version as indicated in the document version history. Touchstone® has also an online Help

system that is accessible from within the software. Help System is a keyword query search and not context-sensitive search, by which a list of pertinent items to the search keywords is provided. There is also a Wiki, which some documentation for user is being stored.

The "*List of All Externally Acquired Hurricane Model Specific Software and Data Assets"* spreadsheet has been reviewed. Per my recommendation, AIR staff added another column for usage status. Some examples of usage status can be if the asset is new, or on-hold for future use.

Enhancements and Florida Commission Documentation Map, which includes version specific updates and enhancements to both Model and Touchstone® was reviewed and verified. This document contains a table that fulfills the Florida Commission requirement from *Section CI-1.D. Computer/Information Standards/Documentation*. This table include a column that itemizes the version-specific changes, and the other columns in this table maps the itemized changes to the pertinent documents in the Computer Standards documentation set C1-C7.

The first set of significant changes were the result of modeling data due to periodical updates from external sources: *Historical* and *stochastic catalogs*, *US Industry Exposure database*, and *ZIP code database*. HURDAT2 re-analysis changes due to inclusion of new historical hurricane events.

Another set of significant changes were building, component and roof age bands to be current as of 2020. This update captures the impact of two years of building and component aging and deterioration since the last model release. Additional related enhancement was the assignment of unknown roof age.

As it mentioned earlier, one structural changes in earlier version of Touchstone was creating a new Model 521 deviated from original Model 21 with the exclusion of precipitation-induced flood module which was added in some point the Model 21.

There were some software enhancements in recent versions of Touchstones. One of these enhancements was updated exposure-weighted grid for disaggregation. Another enhancement was the Min-Max Deductible Policy Logic, which it was discussed and explained by staff.

There were other enhancement items in *Enhancements Table,* which were introduced in the earlier versions of Touchstone®. Some of these earlier Touchstone version enhancements do not impact Florida loss costs or PMLs, but they were listed in the Enhancements table per FCHLPM recommendation. There were no significant formulas or calculation changes this version of Model 521.

Some of these Updates in regard to these changes in the documentation, requirements, data, implementation and testing were discussed. The pertinent C1-C7 Standards were verified for some of these categories, including: documentation, code review, changes history in the source control management tool, requirements, implementation, verification and security.

Standard CI-2: Hurricane Model Requirements

The online central SharePoint repository, *AIRPort*, stores the requirements documentation required for the development of the Model 521 hurricane model as well as Touchstone®. The requirement documents are created for each component and for each software release of Touchstone®, stored and maintained in the document repository.

For the purpose of this Audit, all the requirements document pertinent to the items in *Enhancements* table are viewed. The requirements for newly replacement Model 521 which is incorporated in Touchstone® 2020 included in the "*M521 AIR Hurricane Model for the United States Scope Document for Touchstone 2020*". The motivation and rational for such replacement is explained and any changes are documented.

Requirements for all other enhancements which are incorporated in the Touchstone® 2020 are described in the same document. The requirements pertinent to "roof age" updates and "assignment of unknown roof age" were observed and discussed with staff.

Standard CI-3: Hurricane Model Organization and Component Design

Technical personnel in Research, Modeling, Software Development, and Database groups were present and responded to the questions in regards to the architecture and structure of the enhanced components.

The SharePoint repository provides design documentation for Touchstone and Model M521. A separate Folder for all Flow charts and diagrams were created. There were work on progress to updates some of the existing flowcharts for better depiction of components, functional and logical connectivity and interaction. Some of these enhancements include new symbols and illustration of parallel processing of some components. In addition there exist a spreadsheet for flowchart tracking which listed all flowchart files and their description.

The design document which is referenced by *"Touchstone 2020 Design Document - M521 AIR Hurricane Model for the United States"* link in the enhancement table was briefly reviewed. This was the main document for the latest version of the platform and the Model. Also the flowcharts in two part documents "*Model 521 Porting and Implementation in Touchstone"* which illustrated the workflow among different group was presented in the audit session.

The AIR development staff briefly discussed the Engine and Model interface and how these components are communicated to each other. Related diagrams and documentation for IModel interface was presented.

The design documentation and flowchart associated with the some items in the Enhancement table were reviewed as well. The two new set of 50k and 100K US Hurricane as of 2020 in the document were reviewed and discussed.

AIR hurricane Model is implemented on a single Touchstone platform.

The Network organization was depicted as diagrams in Touchstone System Tires and being reviewed.

Standard CI-4: Hurricane Model Implementation

Developers in Research, Modeling, and Software Development groups were present in the Virtual meeting and discussion was more focused on implementation specifically for the items in Enhancement table. One major structural enhancement in the earlier Version of Touchstone, Touchstone version 8.0, was replacement of the original Model 21 with new derived Model 521, which excludes precipitation-induced flood module. This new Model 521 was inspected in the context of TFS Source control and how these versioning and naming is maintained in TFS.

The updated code snippets for roof age bands and update building and component age as of 2020 was reviewed. Also the code section for Min-Max deductible policy logic was reviewed and discussed. By observing these two new enhanced code, it was advised for better coding styles and adhering to coding standards for better program maintainability, at least for newly created codes by newly joined developers.

One other enhancement is updating internal password controls for communication between the Touchstone application and the SQL Server for fetching data stored in the databases. AIR staff indicated this is a usability enhancement and only from development perspective and not general security.

The programming languages used in development of Model 521 and Touchstone® are: FORTRAN, C++, C# /. NET, SQL, and Java. The coding guidelines have been reviewed as well as sample codes. It is verified that AIR Worldwide maintains the technical documentation, coding standards and guidelines for all the utilized programming languages in the online Document Repository. Nevertheless it was recommended to update those guidelines for missing some coding styles and standards, specifically adding sections and coding style for constants values.

Research and development group were asked to show the codes for new enhancements in C++ and Fortran, and explain these new enhancements. They were also asked to show the history and comparing the new version of the code against previous ones in repository. It was verified sufficient documentation and some comment was provided as well as exception handling. It was advised developer to adhere to coding standards by defining constants for variables whose value is fixed for the duration of the program and utilize it in their program. The developers took the advice and modified the code immediately by defining constants variables for those valued and present it by the end of audit sessions. Also recommended to add more comments in some part of the code.

The Research and Modeling and the Software Development groups use mainly *Microsoft Visual Studio Team Foundation Server (TSF)* for Source control management as well as to track software and documentation change history. The *Microsoft Visual Source Safe (VSS)* still is used for legacy code. During the audit sessions the location and change history of the component in TSF were verified. TFS server version control system provides for comments to be added by the developer each time a change is made and some of those comments for Model 521 were inspected.

The complete documentation set is designed to provide traceability at all levels, including requirements, design, implementation, and verification or testing. All components attributes, i.e. name, creation date, modification date and etc. are being reflected in some source code and definitely in source control repository, TFS.

The development group uses Visual Basic Line-of-Code counter for all its code. The AIR development staff briefly discussed the Engine and Model interface and how these components are communicated to each other. Related diagrams and documentation for iModel interface was presented. They also stated that there were no new equation or Formulas in this version of Touchstone and Model 521. The *Model 521 Equations/Formulas, Variable Mapping, and Crosschecking* document, which discusses the implementation of equations, was presented.

AIR Touchstone runs on a single platform and single Network. It uses the same software stack for each deployment. The hardware, operating system, and essential software requirements are exactly the same for every deployment. The Touchstone Network layout was presented. This Network organization is comprised of client workstations, IIS Application Server, Analysis Manger server, Analysis Engine, database servers, and Model data share. According to AIR staff, Microsoft HPC server as part of Analysis Management Tier, is basically a job manager tool.

Standard CI-5: Hurricane Model Verification

As part of interviews with Research, Modeling and Software Development and QA Groups, the processes for testing and verification of Model 521 and Touchstone® software and data were discussed and reviewed.

It was verified that code for Touchstone®, Model 521 includes statements for error and exception handling as appropriate. The error logging also were discussed.

The overall testing, including user interface and integration testing, is performed using SILK, for automatically verification and comparison. QA staff stated the AIR utilizes ArcGIS geo-processing tool, *Cucumber/ SpecFlow* /*Gherkin* language and *R* analytics environment open source products, as part of general analytics, statistical, geospatial and automated integration and acceptance testing tools. QA teams are also using *ClearQuest* for issue tracking if something fails.

AIR Worldwide has defined general guidelines for testing the Touchstone®. The Software and Model Testing Procedures provided for different test levels: unit testing, integration testing, Module Interface testing and User Interface testing, as well test types: Installation testing, Smoke test, Acceptance test, and Regression test.

The Test Plans that are developed by QA team are accessible through document repository. A high level QA Test Plans for Touchtone documentation, which include test plans for new enhancements has been reviewed.

The *Model 521 Equations/Formulas, Variable Mapping, and Crosschecking* document which contains examples of crosschecking procedures and results for verifying equation was presented during the audit.

The flowchart illustrating Test Process workflow and flowcharts that showing where the validation occurs during the development and implementation processes has been reviewed. Also the Flow charts in two part documents "*Model 521 Porting and Implementation in Touchstone"* illustrate the data validation during several steps of the implementation

QA team explained about Environics analytic used for geospatial validation, and USGC National Land Cover Database for verification.

The verification procedures for new enhancements and version updates were focused for review. QA team displayed the Testing Approach for validation exposure that simulated Min/Max policy deductible scenario. They also showed a test plan and test cases for roof age.

The QA team demonstrated sample test run on Model 521 and showed the test result and its passing/fail status which provided by an email notification.

Standard CI-6: Hurricane Model Maintenance and Revision

AIR Version change management process document in the form of a flowchart was briefly reviewed. The Touchstone® software, model and versioning methodology is documented in *AIRPort*.

Model and Software Revision Policy

A major release of Touchstone® occurs annually. A major release may incorporate new hurricane data from the previous year, improvement in the hurricane model, new user functionality, and possibly new software architecture. Between major releases, AIR Worldwide may releases minor version containing software bug fixes and user functionality enhancements. As of earlier version of Touchstone, Touchstone 8.0 a separate new Model 521 was introduced which was deviated from M21 and started with the version 1.0.0. This new Model 521 was created due to excluding precipitation-induced flood module in the original Model 21.

Source Code, Data and Documentation Maintenance

Microsoft Visual Studio Team Foundation Server (TSF) mostly is used for source control management and to track software and documentation change history. For some Research project or tool, the

Microsoft Visual SourceSafe (VSS) is used. The *TSF* was reviewed in several instances when reviewing the code and structure of the software.

AIR also uses *Microsoft SharePoint* (internally known as *AIRPort*) to manage project, archive and monitor requirements; store and share design plans, and test plans.

The Software Development Group and Research and Modeling group showed some sample of code in and C++ and FORTRAN per request, both in the enhancements and randomly. The code snippets in the enhancements viewed more in detail and recommendation was provided.

Tracking Software and list of model revisions

The tracking tool, *ClearQuest*, is used for all internal clients' ticket, i.e.: project management, logs, defects, revision, enhancement, and change requests assignment tracking. The AIR staff demo this tool in use and the severity feature in the tool per my request.
Salesforce CRM is used for tracking defect, bug, enhancements, and recommendation submitted by clients. The reported defects will be reported and ticketed in *ClearQuest.*

A "version change history" spreadsheet, which includes a list of all model revisions with their dates, as specified in C-6.D of the Computer Standards was presented. A "View Summary Log" option was accessible via a pop up menu.

Standard CI-7: Hurricane Model Security

AIR Worldwide has mandated to comply with its parent company, Verisk Analytics', *Information Security Policy Framework,* enterprise wide definition of fundamental principles for the protection of information resources. AIR *IT* and *Security & Compliance* group works with Verisk Risk & Compliance team to practice and perform these security measures.

The *Information Security Policy Framework* document was reviewed as well as the AIR *IT* and *Security & Compliance* personnel was interviewed. Per this document, designated policy owners of Enterprise Risk & Compliance group review Verisk's information security policies and awareness annually.

Members of AIR *IT* and *Security & Compliance* group, were present during the Audit sessions. They discussed IT Security Management and provided a list of security tools, which comply with Enterprise *Information Security Policy Framework,* and are in various stage of deployment for AIR business. This group also discussed the multi factor authentication, 90 days password change and role based access control. The later restricts network access based on person's role in the organization. They also explained regular security reminders are practiced, as well as security test, like phishing test are exercised. The team reassured that secure FTP servers for obtaining external data sources or internal are used.

The AIR IT and Security team also briefly explained the Emergency Response Team means and process and how the information is secured in safe location in such emergency event. In response to the Covid-19 pandemic question, the AIR IT and Security team, reassured of continuity of all security while staff working remotely.

AIR *Touchstone*® runs on a single platform. The team also presented the *"Touchstone® Installation Guide"* which provides the guidance and practices in user management and access control, anti-virus usage and more.

Areas For Improvement

After observing some of the new code pertinent to items in enhancement table, noticed some coding standards were not practiced consistency, and the coding guidelines needed to be modified to address these coding standards. AIR development took action quickly and modified the code by the end of audit session and they committed to the following actions in future:

- Constitute a recurring training on coding standards for every three months.
- A mandatory training for all the people who would be writing the code.
- Training should cover all programing languages currently being used.

Conclusion

It is my opinion that AIR Worldwide's implementation of Model 521 within Touchstone® is in compliance with the computer standards established by the Florida Commission on Hurricane Loss Projection Methodology. It is also my opinion that the software engineering practices at AIR Worldwide are in accordance with current software industry standards especially with the stipulation of quarterly code reviews.

Curriculum Vitae of Dr. Peter Black, Dr. Robert Contreras, and Dr. Kerry Emmanuel

Curriculum Vitae of Drs. Peter Black, Robert Contreras, and Kerry Emmanuel

Curriculum Vitae

Peter G. Black
Dec 11, 2009

Education

Penn State University	Meteorology, Prof. Richard A. Anthes	Ph.D., 1983
University of Chicago	Meteorology, Prof. Tetsuya. T. Fujita	M.S., 1969
St Louis University	Meteorology, Prof. Edward M. Brooks	B.S., 1964

Professional Experience

Naval Research Laboratory/SAIC, Inc.	Senior Scientist	2007-present
NOAA/AOML	Distinguished Visiting Scientist	2007-present
Naval Research Laboratory/SAIC, Inc	Aircraft Field Program Manager, ONR TCS08/TPARC and TCS10/ITOP Experiments	2007-present
NOAA/AOML/Hurricane Research Division	Director, Hurricane Field Program	2003-2004
NOAA/AOML/Hurricane Research Division	Chief Scientist, ONR Coupled Boundary Layer Air-Sea Transfer Program (CBLAST)	2000-2006
NOAA/AOML/Hurricane Research Division	Lead Scientist, Stepped Frequency Microwave Radiometer (SFMR) surface wind implementation project	1980-2007
NOAA/AOML/Hurricane Research Division	Contracting Officer Technical Rep	1985-present
NOAA/AOML/Hurricane Research Division	Senior Research Meteorologist and Lead Program Scientist	1975- 2007
NOAA/AOML/Hurricane Research Division	Deputy Director, Hurricane Field Program	1975-2001
National Hurricane and Experimental Meteorology Laboratory	Research Meteorologist and Program Scientist, Hurr. Field Prog.	1969-1975
National Hurricane Research Laboratory	Student Meteorologist	1966-1969

Other Experience

- Guest Lecturer, First class of Space Shuttle Astronauts, Lunar and Planetary Sciences Institute, Houston (1981).

- Invited participant, First, Second, Fourth, Fifth and Sixth WMO International Workshops on Tropical Cyclones: Bangkok, Thailand; Manila, Philippines;

Hainan, China; Cairns, Australia; San Jose, Costa Rica; La Reunion, France (1986,1990,1998, 2003, 2006, 2010).

- Expert Witness, Congressional Hearing on hurricane forecasting and surveillance, 1991
- Member, U.S. delegation to Soviet Union on scientific cooperation in tropical cyclone research (1988-1992).

- Invited participant, ICSU/WMO International symposium on Tropical Cyclone Disasters, Beijing, 1992

- Invited participant, WMO International Workshop on Tropical Cyclone Landfall Processes, Macau, China, 2005

- Guest Lecturer, WMO International Training Workshop on Tropical Cyclone Disaster Reduction, Quangzhou, China, 2007

- Scientific editor, CBLAST special issue, *Bull. Amer. Meteorol. Soc.*. 2007

- Invited participant, WMO Second International Workshop on Tropical Cyclone Landfall Processes, Shanghai, China, 2009

Adjunct Faculty Appointments

Naval Postgraduate School	Adjunct Faculty- Ph.D. Committee	2007-present
Univ. of Mass., Amherst	Adjunct Faculty- Ph.D. Committee	2002-2004
Texas Tech Univ.	Adjunct Faculty- Ph.D. Committee	2001-present
Colorado State Univ.	Adjunct Faculty- Ph.D. Committee	1998-present
Univ. of Hawaii	Adjunct Faculty- Ph.D. Committee	1998-present
Univ. of Mass., Amherst	Adjunct Faculty- Ph.D. Committee	1996-1997
Univ. of New York, Albany	Adjunct Faculty- Ph.D. Committee	1995-1999
Univ. of Miami	Adjunct Faculty- Ph.D. Committees	1987-present
Florida State Univ.	Adjunct Faculty- Ph.D. Committee	1984-1988
Univ. of Western Ontario	Adjunct Faculty- Ph.D. Committee	1983-1985

Accomplishments:

Peter G. Back has spent the 40 years conducting hurricane research at NOAA's Hurricane Research Division as a research meteorologist using observations provided by aircraft and satellite platforms. He has been a lead project scientist on various NOAA research aircraft, involving over 400 hurricane eye penetrations in 300 hurricane flights, while responsible for conducting investigations of the hurricane boundary layer structure, ocean response to a hurricane, microwave remote sensing of surface winds, hurricane convective clusters, and most recently, hurricane air-sea interaction processes. He has been the principal scientist on the Stepped Frequency Microwave Radiometer (SFMR), responsible for bringing this surface wind finding instrument from the research to the operational domain. His current

interests are investigations of hurricane air-sea interaction processes, hurricane surface wind and rain rate distributions from airborne passive and active remote sensing and tropical cyclone eyewall mesoscale processes. He was Chief Scientist for the Hurricane CBLAST project from 2000-2006.

Dr Black retired from federal service in 2007 and undertook a position as Naval Research Lab contractor with SAIC, Inc., Monterey, CA. In this new capacity Dr Black was lead aircraft scientist for the Office of Naval Research Tropical Cyclone System-2008 (TCS-08) experiment designed to study Tropical Cyclone (TC) genesis, intensity and structure change in the Western Pacific Ocean (WPAC). The experiment was conducted during Aug- Sept, 2008 from Guam, Marianas Islands. Twenty five flights were flown by the Air Force WC-130J in WPAC systems, including four typhoons, one of which was a super typhoon, in order to diagnose TC genesis, intensity and structure change. Flights were also coordinated between the WC-130J and NRL P3 aircraft. Data were obtained concerning the TC inner core and outer wind structure with SFMR airborne remote sensing instruments and in-situ, air-deployed GPS dropsonde and AXBT observations. Ocean structure conditions were obtained from air-deployed drifting buoy platforms. Dr Black will again be WC-130J airborne science manager for the upcoming ITOP/TCS10 experiment in WPAC during the summer of 2010 that will focus on the ocean response to typhoons.

In addition to these tasks, consulting is ongoing with Air Force Reserve and NOAA Hurricane Research groups concerning validation of the Stepped Frequency Microwave Radiometer (SFMR) on AFRC WC-130J and NOAA WP-3D hurricane reconnaissance aircraft. Consultation with NASA Huntsville instrument development group is also ongoing to conceptualize, plan and test an new instrument, an extension of the SFMR called HIRAD, which would be a scanning version of the SFMR, and be suitable for high altitude manned and unmanned aircraft as well as future satellite applications.

Specific Projects:

- Supervised development of AXBT deployment system for airborne ocean thermal structure measurement for NHRL DC-6, NOAA C-130 and NOAA WP-3D: 1971-1981, and recently for a mobile system installed in the WC-130J aircraft.

- Developed techniques for manned spacecraft handheld stereo photography for Skylab, Apollo Soyuz and early Space Shuttle programs for NASA: 1975-1982

- Assisted in validation of surface wind measurement from space using satellite scatterometry during Skylab and Seasat programs: 1975-1986

- Developed methodology, together with NOAA/NDBC and AFRC/53WRS, for deployment of drifting buoys ahead of hurricanes: 1982-1996

- Refined methodology, together with UCSD/Scripps Institution for Oceanography and AFRC/53WRS, for deployment of drifting buoys ahead of hurricanes and typhoons: 2003-2008

- Managed development of airborne hurricane surface wind measurements from the Stepped Frequency Microwave Radiometer (SFMR) in concert with UMASS, ProSensing, Inc. and NOAA/AOC leading to operational implementation on 13 research and operational hurricane reconnaissance aircraft: NOAA WP-3D (2), AFRC/53WRS WC-130J (10) and NOAA G-IV: 1982-2007

- Managed Hurricane CBLAST project as Chief Scientist leading to new air-sea exchange coefficients for air-sea flux estimation: 2002-2007

- Managed Tropical Cyclone Structure 2008 airborne observations component: 2007-present.

- Developed real-time AXBT deployment and recording system for WC-130J aircraft, and radar recording system, together with Robert Lee, USAF-RET and Jeff Kerling, NAVOCEANO: 2007-2008.

- Managed development of airborne operational Wide-swath Scanning Radar Altimeter (WSRA) for surface directional wave measurement, together with NASA Goddard SFC and ProSensing, Inc: 2005-2007

- Assisted in development of Hurricane Imaging Radiometer (HIRAD) for wide-swath SFMR surface wind measurements in tropical cyclones from aircraft, UAV and spacecraft platforms, together with NASA Marshall SFC, UMICH and USF: 2005-2009

- Manager of airborne observations component of ONR ITOP 2010 experiment

Honors and Awards

1964- Ford Foundation Fellowship
1969- Group Award for participation in Hurricane Debbie Stormfury seeding experiment
1971- Group Award for participation in Hurricane Ginger Stormfury seeding experiment
1974- NASA Group Achievement Award, Earth Resources Experiment Team
1978- ESSA/NOAA Long Term Training Scholarship
1979- Group Award for participation in Stormfury Australian Cyclone Research Mission
1979- NASA SeaSat Science Team Group Award
1993- Dept of Commerce Gold Medal Award (HRD group award)
2002- NASA Group Achievement Award, Fourth Convective Moisture Experiment (CAMEX 4) Science Team
2002- NOAA/OAR Outstanding Scientific paper award
2005- South Florida Federal Executive Board Employee of the Year Nominee
2006- Career Achievement Award, National Hurricane Conference

2007- South Florida Federal Executive Board Employee of the Year Nominee
2007- AOML Certificate of Appreciation for career service
2007- Air Force 'Hurricane Hunter' 53rd Weather Squadron Career Service Plaque
2008- Dept of Commerce Bronze Medal Award-2008
2008- Hurricane Katrina Certificate of Appreciation, U. S. Army Corps of Engineers
2009- Banner I. Miller Award, American Meteorological Society
2009- Awarded status of Fellow, American Meteorological Society
2009- Dept of Commerce Bronze Medal Award
2010- AMS Special Award, Team SFMR

AMS Activities

1956-present- Member, American Meteorological Society
1963- Founding President, St Louis University Chapter, AMS
1966- Secretary, Chicago Chapter, AMS
1972- President, Miami Chapter, AMS
1986-1989- AMS Committee on Air Sea Interaction
2009- present- Fellow, American Meteorological Society

Professional Activities

1970- present- Member, American Geophysical Union
1971-1981- SKYLAB, Apollo-Soyuz and Shuttle Visual Observation Teams- NASA
1975- 1981- SEASAT Scatterometer Working Group- NASA
1996- Chairman, Research Committee, 50th Interdepartmental Hurricane Conference
2009- Member HFIP Working Group for TC observations and analysis

email: rcontreras@arete.com

Education

B. S.	1995	University of California at San Diego (Physics)
M. S.	2001	University of Washington, Seattle (Atmospheric Sciences)
Ph. D.	2004	University of Washington, Seattle (Atmospheric Sciences)

Professional Experience

Areté Associates, Northridge, California (2009-present): Staff Scientist: Develop and implement physical models of signatures, environments, and sensors based on first principles. Develop physics-based algorithms for robust detection and tracking.

Microwave Remote Sensing Laboratory, University of Massachusetts, Amherst (2004-2008): Research Fellow: Responsible for i) research and management of a program on the airborne remote sensing of tropical and midlatitude cyclones and ii) research on the remote sensing of the clear-air atmospheric boundary layer (ABL).

Applied Physics Laboratory, University of Washington, Seattle (1998-2004): Graduate Research Assistant: Investigated the effect of rain on sea surface microwave scattering, included field work, analysis, and modeling.

Department of Atmospheric Sciences, University of Washington, Seattle (2000 & 2002): Graduate Teaching Assistant for two courses on climate and climate change.

Center for Coastal Studies, Scripps Institution of Oceanography, UC San Diego (1995-1998): Programmer/Analyst: Compiled, quality-controlled, and managed coastal meteorological data.

1 The maturity of both Class A-1 and Class A-2 Notes may be extended to 12/15/98 and Class A-1 Notes have a final maturity date of 12/15/08. For details, see text.

OPINION

- Moody's has assigned ratings of **Aaa** and **Ba2** respectively to the Class A-1 Variable Rate Notes ("Class A-1 Notes") and Class A-2 Variable Rate Notes ("Class A-2 Notes") issued by Residential Reinsurance Limited ("RRL"). Incorporated in the Cayman Islands, RRL's sole business purpose is to issue a catastrophe excess of loss reinsurance policy in favor of United Services Automobile Association and USAA Casualty Insurance Company (together "USAA"), a leading personal lines insurer.
- The ratings are based primarily on an expected loss analysis of USAA's underwriting exposure to hurricane risk. In reaching its opinion, Moody's considered the likelihood of insured losses to USAA resulting from a single storm in excess of $1.0 billion, as well as the possible extent of such losses. Losses incurred by USAA in excess of $1.0 billion would trigger payments by RRL to USAA, imposing losses on the noteholders. In addition, the ratings reflect Moody's assessment of USAA's data and claims management practices, as well as the soundness of the transaction's structure and legal documentation. With respect to the Class A-1 Notes, the rating also reflects the credit quality of the collateral.
- *Moody's rating of the Class A-1 Notes addresses only the risk associated with the full return of principal by December 15, 2008.* The principal is secured by a contingent defeasance securities purchase agreement with **Aaa**-rated Goldman Sachs Mitsui Marine Derivative Products, L. P. ("GSMMDP"). *In contrast, Moody's rating of the Class A-2 Notes addresses any possible shortfall in the payment of both principal and interest.*

RATING SUMMARY

Reinsurance Role of RRL

RRL is a limited-purpose corporation organized under the laws of the Cayman Islands. RRL's only business is to provide a one-year catastrophe excess of loss reinsurance agreement (the Agreement) to USAA, the ceding insurer. RRL's sources of funds for the payment of principal and interest on the notes will be the proceeds received by the company from the issuance of the notes, the return from the investment of the proceeds and the reinsurance premium paid by USAA to RRL.

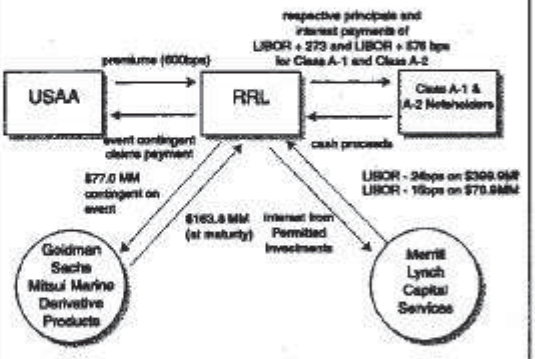
The Agreement provides coverage for 80% of the $500 million risk layer between $1.0 billion and $1.5 billion of insured losses suffered by USAA from a single hurricane during the policy period from June 16, 1997 to June 14, 1998 in the specified U.S. coastal states.

Under the terms of the Agreement, policies in effect as of December 31, 1996, and their renewals are covered. Losses on policies originated after December 31, 1996, are covered but are limited to 9% of losses paid on existing and renewed policies. The Agreement allows USAA sole discretion to determine under which hurricane event to file claims if there are multiple hurricane events during the policy period, each with insured losses exceeding $1.0 billion.

The notes are issued pursuant to an indenture between RRL and **Aa3**-rated Chase Manhattan Bank, the indenture trustee. Of the proceeds from the notes, $399,994,000 will be invested in **P-1**-rated commercial paper collateral. RRL has assigned all rights to the collateral and cash flows (including policy premiums and net swap payments) to a Regulation 114 Trust (the 114 Trust), managed by **A1**-rated Bankers Trust Company in New York as a 114 Trustee for the benefit of USAA. All funds held for the benefit of noteholders are placed in a segregated trust account at Bankers Trust Company in New York. The remaining $76,986,000 of the proceeds will be held for the benefit of Class A-1 noteholders in a segregated escrow account at Chase Manhattan Bank. The 114 Trust is established under New York State insurance regulations. Under the 114 Trust structure, USAA benefits from full statutory capital relief provided by the Agreement.

The notes have been sold globally pursuant to Rule 144A and may be placed off-shore or in the United States where permissible by local insurance regulations. ***In other words, the notes are treated as financial contracts in the relevant markets in which they are sold by the local insurance authorities and are not classified as reinsurance contracts.***

Figure 1
Cash Flow Structure



Transaction Structure

As depicted in *Figure 1*, RRL has issued two tranches: principal protected Class A-1 Notes and principal at-risk Class A-2 Notes. Issuance of Class A-1 and A-2 Notes amounted to $163,800,000 and $313,180,000 respectively.

The swaps between RRL and Merrill Lynch Capital Services convert interest earned on the **P-1**-rated permitted investments to a LIBOR basis in order to make scheduled payments on the notes.

Interest Payments

Interest on the notes is payable on the fifteenth business day of each month commencing July 15, 1997. Class A-1 and Class A-2 Notes carry coupons of one-month LIBOR plus 273 bps and one month LIBOR plus 576 bps, respectively. Interest accrues on the outstanding principal amount of each class and the principal will be adjusted if a loss event occurs.

RRL will invest the proceeds from the notes in **P-1**-rated short-term assets. RRL has entered into two swap agreements with Merrill Lynch Capital Services, Inc. ("MLCS"):

- In the first swap, MLCS receives the interest earnings on the assets from RRL in return for LIBOR minus 24 bps on the risk capital in the 114 Trust – initially at $399,994,000 – adjusted downward as claims are filed during the extension period (as defined below).
- In the second swap, MLCS pays LIBOR minus 15 bps on $76,986,000 in return for interest earnings on that amount.

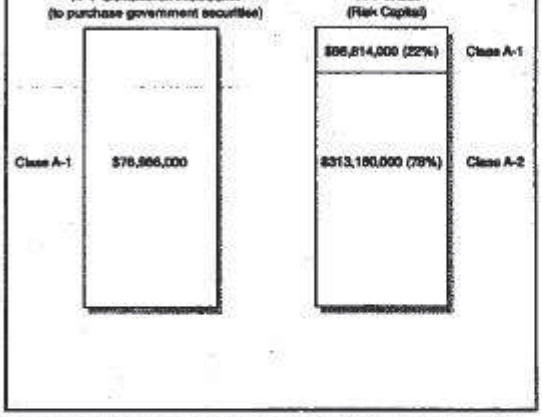
Since the exposure to MLCS on the basis swaps will be small in comparison to the risk from insured events, the rating of MLCS has little impact on the rating of the notes. (MLCS has an implied short-term rating of **P-1** as a result of a guarantee from Merrill Lynch & Co.) The monthly reinsurance premium payable by USAA would be sufficient to eliminate the shortfall between swapped investment earnings from the **P-1** assets and interest owed on the notes, net of fees and anticipated expenses payable by RRL to the claims reviewer, the loss reserve specialist, and other contractual parties to this transaction.

Principal Payments

Repayment of principal in the Class A-1 Notes is secured by the contingent defeasance securities purchase agreement from GSMMDP, while noteholders' rights to the repayment of principal for the Class A-2 Notes depend on the sufficiency of funds held in the 114 Trust, which is a function of ultimate net losses under the Agreement. If a hurricane were to occur during the policy period and result in insured losses in excess of the $1.0 billion threshold for USAA, RRL would be responsible for up to 80% of the reinsurance layer between $1.0 billion and $1.5 billion, while USAA would be responsible for the remaining 20% of the layer.

Figure 2 illustrates the allocation of cash proceeds. Approximately 47% ($76,986,000) of the proceeds from Class A-1 Notes is allocated to the catastrophe contingent purchase of zero-coupon government securities to defease the A-1 Notes by December 15, 2008. The rest of the proceeds ($86,814,000) from Class A-1 Notes is allocated to the 114 Trust account. All the proceeds from the sale of the Class A-2 Notes are allocated to the 114 Trust account; therefore, the total risk capital available to USAA from the account amounts to $399,994,000.

Figure 2
Allocation of Cash Proceeds



Payments for eligible claims are drawn against the 114 Trust and allocated on a pro rata basis between Class A-1 and Class A-2. Once a payment is made from the 114 Trust, **Aaa**-rated GSMMDP is obligated to deliver cash sufficient to purchase any combination of government securities needed to redeem the full face value of the Class A-1 Notes by December 15, 2008. However, failure by USAA to pay premiums to RRL at any point in time is considered an event of default under which both classes of the notes will be accelerated.

Claims Management Procedures

An important aspect of Moody's rating process is an assessment of the reliability of policy data and the procedures in place to ensure that if a major hurricane were to occur, USAA's insured losses could be accurately measured.

Under the structure, once a hurricane has occurred, USAA may present proof of claims to the 114 Trustee, if any, on a monthly basis commencing April 15, 1998. USAA is required to pay a one-time special premium when it first presents the claims to ensure that the independent auditor, KPMG Peat Marwick Cayman Islands ("Peat Marwick"), can verify claims without incur-

ring extraordinary unreimbursed expenses. The claim amount will be calculated as A) the sum of (i) losses incurred for existing policies and renewals in force as of December 31, 1996, plus (ii) losses under new policies, but in no event exceeding 9% of the losses under existing and renewed policies, (B) multiplied by 102% to account for maritime losses, and (C) such product multiplied by 102% to account for administrative expenses.

The proof of loss claims will be reviewed and processed by Peat Marwick. Moody's has reviewed the agreed-upon procedures that Peat Marwick has contracted to perform. The procedures include the selection of a statistical sample of the claims and verification that the claims are legitimate and meet the terms of the policy coverage and the Agreement. The auditor will also verify the paid claims amount against documentation in the claim files. This step provides a quality check to ensure that only covered claims are paid.

If USAA believes that additional time is needed to present claims to RRL beyond the policy period, it may elect to extend the claims filing and verification period until December 15, 1998, by paying an extension premium to RRL. Under these circumstances, if USAA still has unpaid claims (to policyholders) outstanding, it may submit its loss reserve estimate to RRL. RRL has engaged Ernst & Young ("E&Y") as an independent loss reserve specialist that will provide an independent loss estimate for claims not yet reimbursed. Both USAA and E&Y will have the opportunity to review each other's estimate and submit a final loss reserve estimate. The lower of the loss estimates will be utilized for the purpose of calculating the unpaid claims and will be binding on RRL.

At the end of the extension period, the outstanding collateral in the 114 Trust will be liquidated, and the remaining proceeds will be divided proportionately between Class A-1 and Class A-2 noteholders. If the aggregate of the Class A-1 collateral account, together with the pro rata share of proceeds from the 114 Trust, is at least equal to the face amount of Class A-1 Notes, the total proceeds will be disbursed to Class A-1 holders. Otherwise, Class A-1 noteholders may have to wait until December 15, 2008, or the earlier date on which the government securities will mature to yield the full principal of Class A-1 Notes. Class A-2 holders receive their disbursement at the time their pro rata share of the 114 Trust collateral is liquidated.

Moody's believes the policy data collected by USAA are consistent with the best industry practices and, together with Peat Marwick's certification of the reliability of the data for the purpose of this transaction, is comfortable with the data's integrity. While no procedure is totally bullet-proof, Moody's believes the claims management procedures in place are sound and, when coupled with USAA's retained share of 20% of the risk layer, act as a reasonable check against the risk of inflated claims.

Modeling and Quantitative Aspects of the Rating

The quantitative component of Moody's rating process focused on a rigorous determination of the notes' *expected loss* relative to the respective promises made to investors. The resulting rating thus combined the probability that USAA's hurricane losses might exceed $1.0 billion, together with the expected severity of investors' losses. The **Aaa** rating of the Class A-1 Notes (with repect to the promise of repayment of principal only), and the **Ba2** rating of the Class A-2 Notes were arrived at by *benchmarking* the expected losses against those of conventional fixed-coupon corporate bonds, as determined by Moody's default data.[2]

In turn, the expected loss numbers were derived by making use of the work done by Applied Insurance Research ("AIR"), a consulting firm specializing in the scientific modeling of insurance perils, which had been retained by the issuer for this purpose. Ultimately, AIR provided Moody's with an "exceedance curve" which gave, for every relevant dollar amount, the probability that USAA's hurricane losses would exceed that amount.

Moody's did not simply accept AIR's modeling results at face value. Rather, we followed an examination and calibration procedure, aiming to provide Moody's with a high degree of confi-

2 See "Moody's Refines Its Approach to Rating Structured Notes," Moody's *Special Comment*, July 1997

dence in the reliability and stability of the simulation results. In particular, we:

- Examined the historical data used by AIR.
- Identified key parameters and asked that they be stressed to reflect uncertainty.
- Calibrated AIR's results by reviewing out-of-sample forecasts and comparable results by other modeling firms.

Examination of Historical Data

Our initial step was to address potential concerns regarding the completeness and soundness of the historical data used as input in AIR's model. In response to our concerns, AIR was able to demonstrate to our satisfaction that no bias was introduced by treating events that occurred prior to the advent of modern measurement technology on an equal footing with those that succeeded it. Furthermore, we were convinced that the scope of the data sufficed to account for most of the potential clustering and other statistical phenomena that might be exhibited by the time series, and that, in any event, the nonlinear nature of the underlying dynamics all but prohibits the long term predictability of cycles and trends that may exist.

Review of Key Assumptions

Proceeding from the primary step in our analysis, Moody's next examined AIR's assumptions regarding the methodology's key variables. For example, given that *hurricane frequency* is clearly a crucial input, we considered the validity of fitting a particular distribution to the historical record, versus that of a nonparameteric alternative that might capture more accurately the nuances in the data. Once satisfied with the parametric approach, we viewed the consequences of reparametrizing this distribution to be centered around a standard deviation away from its historical mean.

In analyzing the impact of another fundamental component, the storm's *central pressure*, we investigated the consequences of replacing the selected distribution with a "fatter tailed" alternative, thus providing for a higher likelihood of extreme events. We also sought to understand the dynamic equations that govern variables such as *forward wind speed* and the continuity assumptions made about the particular solutions chosen. Here, in addition to our interest in studying the stressed numbers, we also looked for the changes resulting from the stress to have been moderate, thus indicating an inherent stability in the underlying methodology. To this end, we investigated the ability of a Monte Carlo simulation to adequately capture the full spectrum of potential outcomes.

Another important variable evaluated by Moody's is *demand surge*, which refers to the increase in basic material and labor costs in the aftermath of a major catastrophe. Past catastrophe losses have shown that demand surge is a very important factor that drives the ultimate reported losses. Moody's notes that demand surge is an increasing function of the magnitude of the industry losses: the more severe the catastrophe, the higher the demand surge factor expressed as a fraction of total losses. Property and casualty industry experience with the past few storms in the Category Four to Five range has shown that demand surge can induce up to an additional 25% in reported losses, an assumption applied here.

Calibration of AIR's Results

Moody's was able to conduct a calibration test of a portion of AIR's model through the availability of AIR's past performance in forecasting the damage that would be caused by incoming storms. Specifically, upon the approach of a hurricane (typically about three days before landfall), AIR is normally asked to estimate the insured damages that will ensue once the storm hits land and proceeds along its track. We found that for 9 of the last 13 major U.S. storms, AIR's model came within 20% of the losses reported six months later by the relevant state department of insurance or other reliable sources. (Final figures are only available several years later.)

Since the USAA study of exceedance probabilities invokes this same model but applies it to many different scenarios, Moody's was able to conclude that errors in estimation, while inevitable in certain particular cases, would be significantly reduced when averaged out across numerous simulated cases. ***One should note, however, that this calibration exercise applies only to process of associating claims with a given storm, not to storm prediction itself.***

A second approach to stress testing is to compare AIR's results to those of other consulting firms. In this transaction, Moody's used an available report for the Florida Commission on Hurricane Loss Modeling. The report showed estimated losses simulated by four different consulting firms, including AIR, for various locations and property categories against a uniform set of sample input data. An alternative form of stressing AIR's results is the scaling of AIR's loss estimates to match those of the most conservative of the four firms.

Finally, Moody's examined the background of the members of AIR's staff. We also examined the validation reviews provided by industry experts regarding AIR's model. Both suggested that the model used in the USAA exercise meets appropriate professional standards.

From these various stress analyses, Moody's finally applied the results of the re-estimated storm frequency count – the most onerous stress – to the *base case* as originally supplied by AIR. Using the results from the Florida Commission on Hurricane Loss Modeling, Moody's also took account of the variations in the loss estimates of the four modeling firms based on a defined set of inputs. This gave rise to an *adjusted exceedance curve* from which expected losses, and ultimately letter ratings, were derived as described above.

It should be emphasized that the application of these stressed assumptions is not intended to arrive at a "conservative" measure of expected loss. Rather, the goal is to reflect, to the extent possible, the uncertainties inherent in the modeling process that most likely prevent a more precise determination of the expected loss.

Legal and Bankruptcy Considerations

Moody's rating analysis includes an assessment of structural and legal risks to investors. Of particular importance is the perfection of the security interest in the collateral for the benefit of the both Class A-1 and Class A-2 noteholders.

The proceeds are held in trust by Bankers Trust Company pursuant to the Regulation 114 Trust Agreement for the benefit of noteholders and, if there are any insured losses in excess of $1.0 billion, for USAA as well. The collateral is maintained at a segregated account at Bankers Trust New York. Based on the segregation of collateral account; the credit strength of Bankers Trust and Chase Manhattan Bank – the 114 Trust trustee and indenture trustee, respectively – and the transaction's legal documentation, Moody's believes that the rights of noteholders to the pledged collateral would not be impaired.

New York law grants certain irrevocable rights to the reinsured party under a Regulation 114 reinsurance agreement. These provisions would enable USAA, under limited circumstances, to withdraw funds from the Regulation 114 Trust not otherwise payable to it under the reinsurance agreement, notwithstanding the noteholders' security interest. The Agreement requires reimbursement from USAA, plus payment of a penalty charge, for any such withdrawals. Regulation 114 also stipulates that, in an event of USAA bankruptcy, (which is unlikely given their current insurance financial strength rating of **Aaa**) all amounts payable will go to an appointed liquidator. In light of our review, Moody's is of the opinion that the occurrence of these events is remote.

An additional protection for the noteholders is the restriction imposed on RRL against issuing any other debt or reinsurance agreement. This feature protects the noteholders from facing other creditors or bankruptcy proceedings initiated by others that may impinge on their rights.

As a licensed reinsurance company incorporated in the Cayman Islands, RRL is subject to regulation by local authorities. Moody's has reviewed the legal opinions provided for the transaction and believes that the noteholder interests will not be impaired by actions of the Cayman Islands insurance regulator or any other authorities operating in relevant jurisdictions.

■ *Summary*

Residential Reinsurance Ltd.'s (Residential Re) $477.0 million catastrophic risk-based notes are rated as follows: $163.8 million class A-1 notes, 'AAA'; and $313.2 million class A-2 notes, 'BB'. The notes were privately placed on June 16, 1997 and are eligible for resale under Rule 144A of the Securities Act of 1933.

The 'AAA' rating reflects the 100% principal defeasance on the class A-1 notes. The rating addresses the likelihood that investors will receive payments in accordance with the terms of the trust indenture, which does not provide for interest payments in the event of a loss occurrence.

The 'BB' rating was derived using Fitch's catastrophic risk-based bond methodology, which incorporates a review of the ceding insurer's relevant policy data and underwriting plan, the catastrophic risk model, and the note structure. The 'BB' rating addresses the likelihood that investors will receive timely payment of principal and interest, i.e. the likelihood of a loss occurrence.

Approximately $77 million of the note proceeds will be held in a defeasance account, with the remaining $400 million providing reinsurance coverage to United Services Automobile Association and USAA Casualty Insurance Co. (collectively, USAA) in the event of a loss occurrence. A loss occurrence is defined as a hurricane, occurring between June 1997 and June 1998, that is classified as class 3, 4, or 5 on the Saffir-Simpson scale; occurs on the U.S. eastern seaboard or in the Gulf states; and results in USAA policy losses exceeding $1.0 billion. The notes provide reinsurance within the $500 million risk layer in excess of $1.0 billion.

The $1.0 billion risk transfer point is referred to as the "trigger point" of the notes and represents the point at which 80% (calculated as $400 million at-risk principal divided by $500 million risk layer) of loss beyond $1.0 billion is transferred to the noteholders. USAA is required to maintain a 20% risk of loss within this risk layer. Loss claims will be drawn pro rata among class A-1 at-risk principal, class A-2, and USAA.

Fitch applies a three-tiered approach to assess catastrophic risk-based bonds, incorporating: a detailed review of the claims procedures and underwriting standards of the ceding insurance company (USAA), its policy book of business, and the data input to the catastrophic event model; a review of the catastrophic event model and expected loss probabilities; and a review of the notes' collateral structure and the corresponding legal documentation.

In its review of USAA's catastrophic event management process and relevant policy data, Fitch identified policy nuances that previously had not been incorporated into the catastrophic event model. To address these changes, Fitch adjusted the trigger point to effectively reduce the risk transfer level and, thus, reduce the notes' rating level. This hypothetical trigger point is referred to as the "attachment point."

The quantitative analysis is based on a review of the catastrophic event model (referred to herein as the AIR Model) and of the catastrophic modeling firm, Applied Insurance Research, Inc. (AIR). AIR was engaged by Residential Re to apply its existing hurricane simulation model to assist in determining a bond rating. The model's adjusted output was used as the basis for Fitch's calculation of the expected probability of loss.

Using probability distributions based on historical hurricane data, the AIR Model simulated thousands of hypothetical hurricane scenarios with varied geographical locations and storm characteristics. These scenarios were then applied against the portion of USAA's book of business covered by the bond to determine expected loss. The AIR Model did not simulate a specific hurricane occurrence, but focused on generating long-run average expected loss. Based on its testing of the AIR Model, Fitch incorporated alternative distribution assumptions into its rating analysis. Fitch also performed validation testing, reviewing the AIR Model's performance in estimating loss resulting from past catastrophic events. The result of this analysis was a graph plotting expected loss against probability of loss, referred to as the "exceedance curve."

The adjusted attachment point was then applied to the exceedance curve to determine the probability of incurring a loss at the attachment point level. Sensitivity testing around the attachment point determined a range for the expected probability of default under the notes. Fitch compared the probability of default to the historical default probabilities on corporate bonds to determine a base rating range. Qualitative factors were incorporated into the rating to reflect structural and credit issues associated with the notes to arrive at the final ratings.

Rating Process for Book of Business Bonds

1. Review ceding insurer's underwriting, claims management, and policy data.
2. Adjust attachment point to incorporate insurance issues not captured in the catastrophic model data input.
3. Conduct due diligence on the modeling company.
4. Review probability distribution assumptions, certain data mathematical functions, model specification, and estimation/simulation techniques used in developing and applying the model.
5. Run sensitivity tests to alternate distributions, location vulnerability, and sample size. Apply modified distribution functions to better fit the nature of the data.
6. Use model output to graph an exceedance curve (as adjusted in steps 4 and 5).
7. Apply adjusted attachment point to exceedance curve and perform sensitivity testing around that point to determine the range of long-run probability of loss.
8. Compare probability of loss range to historical losses on corporate bonds.
9. Review bond structure, counterparty risk, and legal documents.
10. Incorporate credit factors relating to the ceding insurer and the bond structure into final rating.

■ *Review of Ceding Insurer/Policy Data*

USAA

USAA is a leading insurance and financial services organization and one of the largest property and casualty companies in the U.S. USAA has historically served a military niche by providing financial services to officers of the U.S. military, their families, and some other associated groups. In 1996, USAA expanded its eligibility requirement to include enlisted military personnel. USAA has a long-standing history of excellent financial strength and of maintaining the highest credit quality, which provides qualitative and counterparty credit to the notes.

Data Quality and Policy Coverage

Fitch reviewed each relevant policy type in USAA's portfolio and further reviewed the data input to the AIR Model for thoroughness and accuracy.

Through this review, Fitch identified individual policy characteristics that had not been incorporated into the model, which used policy data as of Dec. 31, 1996. To incorporate these characteristics into its risk assessment, Fitch applied mathematical adjustments to the trigger point that effectively reduced the bonds' risk transfer level. These adjustments, as outlined below, reduced the trigger point used in Fitch's analysis by approximately 16%.

Attachment Point Adjustments

Policy Forms: Many policies contain riders that would allow a policyholder to increase the amount of coverage above the property's total insured value (TIV). Specifically, policy riders are available that would insure up to 125% or 150% of TIV or an unlimited amount equal to the true replacement value. Fitch analyzed the impact of these riders by state, weighted by the amount of potential policy loss incurred. The final reduction to the attachment point for policy forms was approximately 1%.

Existing Policy Growth Factor: Policies in force as of Dec. 31, 1996 could increase loss coverage due to building cost endorsements, increased replacement cost from additions to the dwelling, changes in deductibles, the addition of policy riders, and changes to the replacement value of contents. Conversely, natural attrition would offset this growth, and nonrenewals are expected to be minimal due to USAA's high persistency ratio (almost 98%). The attachment point was reduced by 3% (5% growth less 2% attrition) to address potential growth in the Dec. 31, 1996 book of business.

New Policy Growth Factor: The notes also provide reinsurance for new policies written after Dec. 31, 1996. These policies must be written during the term of the reinsurance agreement and cannot be written after a loss occurrence. Under the reinsurance agreement, loss payments resulting from new policy growth will be capped at 9% of the loss payments from existing policies. Fitch analyzed the growth in insurance in force for key states covered by the USAA book of business and found that, for the nine months ended Dec. 31, 1996, insurance in force grew 7.2% to 9.6%. Fitch further assessed the effects from inclusion of all military personnel in USAA's customer base and consequently applied the maximum 9% factor to reduce the attachment point.

Percentage Loss Factors: Pleasure boat and inland marine floater policies, as well as USAA's loss adjustment expenses in processing claims, were incorporated into the data by assigning a percentage loss factor. Fitch adjusted the attachment point by 2% for each of these factors, as specified in the reinsurance agreement.

The table below left summarizes Fitch's insurance policy adjustments that resulted in the final attachment point used in the rating analysis.

Demand Surge

In the wake of a catastrophic event, demand for building materials and labor soars, frequently leading to price increases known as "demand surge." According to industry sources, demand surge after Hurricane Andrew was approximately 12% in excess of market prices. The AIR Model incorporates a demand surge factor that varies according to the devastation caused by each storm and can result in cost increases of 20% to 25% for a very large storm loss. No further adjustment was required by Fitch.

Underwriting and Claims Process

Fitch reviewed USAA's underwriting practices, reinsurance accounting systems, catastrophic event management, and claims review process. Overall, USAA exhibits conservative underwriting standards and effective, timely claims management procedures, particularly in response to catastrophic events.

Fitch examined USAA's underwriting quality to confirm historical consistency and future trends. To proactively manage windstorm risk, USAA has limited or restricted homeowner policies in high-risk areas. Examples of such limitations include increasing deductibles, limiting policy option availability by state, periodically halting marketing activities in Florida (which effectively limits policy growth to renewals and organic growth), eliminating mobile home insurance, and eliminating unlimited replacement value homeowner policies.

Attachment Point Adjustments

USAA – United Services Automobile Association/USAA Casualty Insurance Co.

USAA's catastrophic management process incorporates a sound action plan that mitigates ultimate losses. USAA's catastrophic response team is well-managed and relatively effective. In the event of a catastrophic loss occurrence, this team is dispatched immediately to the loss site to assess damage and settle claims. By arriving early in the loss assessment process, USAA avoids the full impact of demand surge and reduces additional living expenses by expediting repairs.

Fitch found that USAA's claims review process accurately estimates claims. USAA cited Hurricane Andrew as an example of its catastrophe claims review process, noting that approximately $125 million was collected from reinsurers without dispute over claims-paying practices. Proof of loss claims presented on note proceeds will be reviewed by KPMG Cayman Islands.

With respect to loss timing issues, Fitch found USAA to be responsible in assessing loss and promptly honoring claims. Fitch expects that, in the event of a loss occurrence, USAA will be able to process and settle claims within the time period allowed by the documents. Fitch reviewed the reinsurance accounting process at USAA and believes that the reinsurance reports contain the appropriate sections to track and report policy losses for the notes.

The table below summarizes the five hurricanes resulting in the greatest amount of ultimate loss for USAA since 1974, as well as the duration of payment on loss claims.

■ *Catastrophic Event Modeling*

The primary goal for any catastrophic model is to calculate a distribution of expected losses as a reasonable proxy for actual loss. The stochastic model developed by AIR uses empirical observations of hurricane events to simulate storms that generate a range of alternative scenarios. These scenarios involve catastrophic events of varying magnitudes and at various geographic locations. The model output is susceptible to varying degrees of model risk.

To verify the reliability of the model output, Fitch performed a review of AIR and conducted model diagnostics, validation testing and sensitivity analysis to assess the robustness of model estimates.

Applied Insurance Research

AIR is an independent consulting firm that develops catastrophic risk assessment of natural events for the insurance industry. Since its 1987 formation, AIR has provided catastrophe loss analysis services for more than 65 primary insurance companies and over 70 reinsurance companies. Many of these companies use AIR's catastrophe risk assessment and management methodologies on an ongoing basis. AIR modeling data are used by USAA in its underwriting strategy and the determination of capital adequacy.

AIR Model — Overview

AIR employs a Monte Carlo simulation approach to estimate the likelihood of hurricane occurrences (model frequency) and to approximate key parameters that influence a storm's force and duration (storm intensity). These simulated storm values are applied to the TIV at various geographic locations to estimate the damage in those locations as a function of USAA's book of business (location vulnerability). As the basis for simulating these events, the AIR Model uses data representing USAA's book of business at the policy level and technical and meteorological analysis.

The model simulates thousands of storm scenarios with various frequency, intensity, and vulnerability parameters. These scenarios are assumed to represent the range of possible outcomes to compute the likelihood of a catastrophe of a given magnitude and loss. Estimated losses are calculated by quantifying the interaction between observed event occurrence characteristics and structural limits, demographic concentrations, and policy types. The result is the exceedance curve, which plots the related policy loss given the probability and severity of a catastrophic event occurrence. These points are used to identify an attachment point for the transfer of losses effectively from the ceding insurance provider to the bondholder. The box on page 5 outlines a procedural overview for the simulation.

Model Diagnostics

Fitch evaluated the underlying technical integrity of the AIR Model on the basis of model specification and model structure.

Model specification involves the selection of distributional assumptions and

Hurricane Loss Experience

AIR Hurricane Simulation Model Procedure

1. Sample a probable value for the annual number of hurricane landfalls, assuming a negative binomial distribution.
2. Sample a range of probable values for storm intensity such as central pressure differential and maximum wind radius. These values are used to compute maximum wind speed, a primary driver of hurricane damage.
3. Simulate storm location and movement by sampling landfall locations, forward speed, and track direction values.
4. Compute relative wind speeds at the zip code level, based on terrain at landfall and time decay after landfall.
5. Apply simulated storm damage coefficients to USAA's book-of-business exposures (by zip code and according to structural damage classifications and policy type, among other things).

Repeat the procedure several thousand times, cumulating the results over repeated simulations to compute the average long-run expected loss. The calculated catastrophic loss distribution can be defined as an estimate of expected long-run policy losses, given a geographical distribution of property exposures.

parameter estimation. Fitch tested the appropriateness of probability distributions assumed by AIR and the estimation methods employed to fit the parameters of those distributions. Based on the results of sensitivity testing, Fitch modified the AIR Model by incorporating alternative distribution assumptions into its final rating analysis. These alternative distributions are further described under Sensitivity Testing above right.

Model structure assessment involves both model design and procedural implementation. Fitch reviewed the mathematical functions used in the model to approximate the interactions between simulated storm parameters. Fitch found these parameters to reasonably and adequately represent event characteristics, according to current academic and industry practices. Some of these parameters were modeled as probability distributions, while others were functions measured or derived from current research. Storm parameters accounted for in the AIR Model include landfall location, storm intensity bounds, central pressure differential, maximum wind radius, forward storm speed and track direction, time and surface wind decay, and relative wind speed.

Model Robustness

Fitch tested model robustness to assess the reliability of model estimates as long-run averages of event occurrences and magnitudes. The two elements of model robustness are process risk and parameter risk. Process risk is minimized when hypothesized assumptions reasonably represent the true behavior of actual events. Parameter risk is minimized as the number of simulated draws from a distribution is increased. If process risk has been minimized (i.e. the hypothesized assumptions are appropriately selected and well estimated), as the number of iterations become sufficiently large (i.e. as parameter risk is minimized), the simulation estimates should converge to the long-run behavior of the actual physical phenomena being modeled.

After a review of the model, Fitch concluded that 10,000 simulated model "years" and 17,500 simulated storms adequately account for parameter risk. However, in evaluating process risk on the basis of selecting distributions and estimating parameters, Fitch found the AIR Model and the resulting loss distribution to be overly sensitive to tail specification. Tail specification is the critical factor for the reliability or robustness of the model estimates as long-run averages of loss occurrence.

Sensitivity Testing

To arrive at a level of comfort regarding process risk, Fitch evaluated the robustness of the AIR Model estimates using outlier analysis, empirical evaluation (out-of-sample/back testing), and simulation-sensitivity analysis using alternate distributions.

Outlier Analysis: As a test of loss sensitivity to tail specification, Fitch applied previous occurrences of extreme severity to TIVs from USAA's current book of business. Fitch also directed AIR to simulate storm events in specific regions with high concentrations of insured exposures and assess the resulting losses. These worst-case scenarios included moving Hurricane Hugo from Charleston to Miami and varying the landfall for Hurricane Andrew by 50–100 miles. Fitch then reviewed this output related to location vulnerability and concluded that this was further evidence for assuming a fatter-tailed distribution related to storm intensity and loss severity *(see Vulnerability and Damage Estimates, page 7).*

Empirical Evaluation: Although the purpose of the AIR Model is not predictive in nature, one approach to establishing model robustness is to test the model for predictive power against observed events. To evaluate model performance, Fitch reviewed performance data comparing model simulations to actual specific storm events. Fitch's comparison of AIR Model estimates to actual large storm loss occurrences found model estimates tended to be within 20% of actual USAA losses for observed events.

Simulation-Sensitivity Analysis: Fitch performed a sensitivity analysis of the model to simulations employing alternate distribution assumptions for frequency and intensity of storm occurrence.

1. Model Frequency Estimates

Given the inherent randomness of hurricane occurrence, a probability distribution assumption is inferred from observed past occurrences to estimate the long-run likelihood of occurrence. For model frequency estimation, AIR uses the maximum likelihood estimation (MLE) with more than 90 years of historical data to fit the parameters of a negative binomial distribution. AIR employs a chi-squared test to assess the goodness of fit of the negative binomial parameter estimates. Values are then sampled from the specified distribution using the Monte Carlo technique to generate model rates for annual hurricane occurrences.

To fit the parameters of the assumed (negative binomial) frequency distribution, AIR employs the full 96 years (1900–1996) of recorded U.S. hurricane data. A competing approach considers a shorter period of more recent data (post-1926) to be more representative of future occurrences. The basis for this approach is the theory that hurricane occurrences are not necessarily independent, but occur in cycles, and that data quality has improved over time, with reduced measurement error. Fitch assessed the sensitivity of the model estimates to sample estimates of hurricane frequencies based on the more recent data. This "short sample" sensitivity was incorporated into Fitch's rating analysis, as illustrated in the table below.

2. Storm Intensity Estimates

Central pressure differential influences maximum windspeed and, thus, is the primary factor in determining hurricane wind damage. For the estimates of storm intensity, AIR uses the MLE method to fit the parameters, and the chi-squared method to test the fit, of a Weibull distribution, in contrast to the use of the negative binomial distribution for frequency estimation. However, without further tail specification, using the MLE and chi-squared test for distributions that are not asymptotically normal (i.e. do not become normal by increasing the number of observations) can result in estimates that are sensitive to fatter tailed distributions. The MLE is appropriate for the negative binomial distribution, which is asymptotically normal. Since the Weibull distribution is not asymptotically normal, using the MLE to estimate the parameters of the distribution can misspecify the tails of the distribution. In other words, the model as given may understate the expected magnitude of storm occurrences.

To address this issue, Fitch conducted a sensitivity analysis using modified model frequency and storm intensity distribution assumptions. To measure the sensitivity of the storm intensity estimates to misspecified tails (i.e. underestimated extreme values), Fitch employed a modified specification that fit central pressure data to a lognormal distribution, which has a fatter tail than a Weibull distribution. Based on its analysis, this "lognormal sensitivity" was incorporated into Fitch's rating analysis, as illustrated in the table below left.

The table below left summarizes the results of these sensitivities, compared to AIR's base case. This table also includes a worst case, which combines the short sample with the lognormal sensitivity. All three sensitivities were run at the unadjusted $1 billion attachment point; thus, results are for comparative purposes only. Fitch's final rating incorporated an adjusted attachment point, as described earlier. Fitch concluded that losses are more sensitive to alternate distribution assumptions for storm intensity than for storm frequency.

Short Sample Sensitivity: Employing AIR's base case distribution assumptions with the more recent (short) sample increased the number of storms, creating losses above the attachment point, but reduced the probability of loss. In effect, the number of storms increased and the intensity decreased. The result was a slightly lower probability of loss (0.90%) and moderately lower cumulative expected losses (0.53%) relative to AIR's base case.

Lognormal Sensitivity: Estimations using a lognormal distribution in place of the Weibull, while assuming all other base case assumptions, increased the number of storms creating losses above the attachment point and the probability of loss. In effect, the number and intensity of hurricanes increased. This increased the probability of a loss occurring (1.43%) and the cumulative expected loss (0.97%) relative to the base case.

Short Sample and Lognormal Sensitivity: As a worst-case sensitivity to gauge the relative contribution of each of these

Sensitivity to Alternate Assumptions

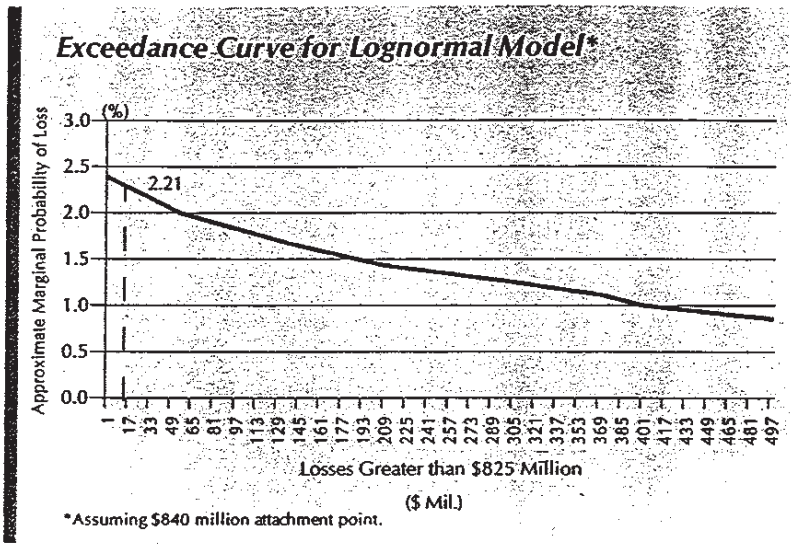
(At $1 Billion Attachment Point)

	Base Case	Short Sample	Lognormal	Short Sample and Lognormal
No. of Storms	163	180	250	334
Loss Probability (%)	0.93	0.90	1.43	1.67
Expected Severity ($ Mil.)*	336	296	339	334
As % of Risk Tier	67.18	59.22	67.80	66.71
Expected Loss (%)	0.63	0.53	0.97	1.11

*Above the $1 billion assumed attachment point.

alternate assumptions, Fitch combined the short sample with the lognormal distribution estimation for storm intensity. This increased the frequency and intensity of storms even further. Therefore, probability of loss and cumulative expected loss increased over the lognormal case by 0.24% and 0.14%, respectively.

Based on these sensitivity results, Fitch used the lognormal case, which employed the data from the longer sample period and assumed a lognormal distribution for storm intensity, in its final rating analysis. Fitch believes the lognormal distribution better captures the variability related to storm intensity data and that a frequency distribution estimated from a longer sample is more robust.



Vulnerability and Damage Estimates

To determine expected loss resulting from simulated frequency and intensity parameters, the AIR Model computes damage estimates by applying storm output values to location and insurance data based on uniform landfall distributions. This approximates tracking simulated storms through various locations. Factors incorporated into vulnerability estimates include:

- Damage and loss computed as a function of zip code-level insured values and distance from the radius of maximum winds. The use of zip code-level data introduces li ness into the model in the co tation of local damage as a fun of landfall.
- The vulnerability of structura tures.
- Policy data as supplied by US
- Demand surge, as fit to local increases during Hurricane drew. This function attemp capture the effects of short- supply/demand imbalances r ing from hurricane-related ma and labor shortages and opportu pricing and reflects immediat creases to replacement costs.
- Inflation-adjusted long-run gr in replacement costs.

Overall, Fitch found AIR's location nerability methodology to be re able and appropriate. To assess sensitivity of damage estimates to nate landfall locations, Fitch inc rated the results of its outlier analy evaluating the impact of location nerability on loss severity *(see O Analysis, page 5)*.

Aggregate Loss Distribution

Using the lognormal case as its r case, Fitch developed an int model that used points provide AIR to construct an approximate

Expected Loss Determination

1. Losses from events of specified magnitude are weighted by the likelihood of occurrence to determine expected losses, as follows:

   {odds of event at loss level}*{the incremental loss incurred by that event}.

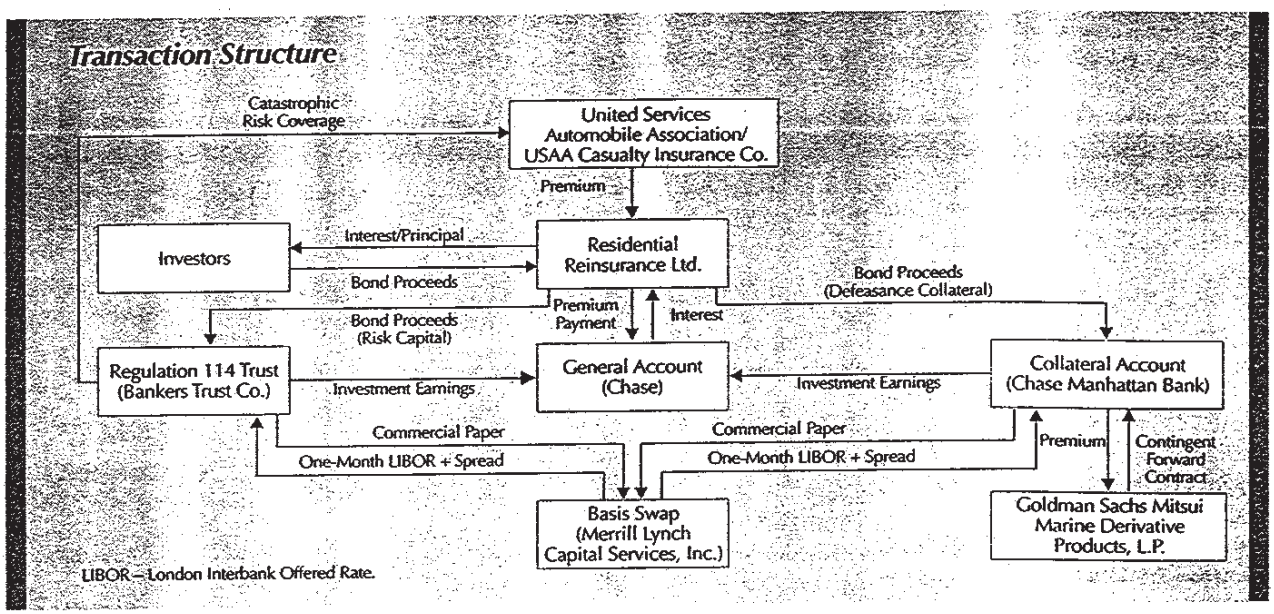
2. These weighted values are then summed.
3. The sum of the weighted values is divided by the total number of loss events to determine expected loss severity, as follows:

   {expected losses}/{total number of loss events}.

4. The cumulative probability of loss (the sum of event increments contributing to each specified loss level) is multiplied by the expected loss severity (as a percentage of principal at risk) to determine cumulative expected loss, as follows:

   {cumulative probability of loss}*{expected loss severity}.

5. The cumulative expected loss value is compared to corporate bond defaults/recoveries to assign a base rating that can be adjusted to incorporate other qualitative measures.



ceedance curve using linear interpolation. The objective of the exceedance curve is to graph expected losses, at or around the modified attachment point, against the probability of event occurrences at various levels of magnitude. Based on its sensitivity testing, Fitch analytically modified the slope and convexity of the exceedance curve to reflect bias in model estimates of loss, as well as the adjustments to the attachment point.

Expected Performance

Using the points on the exceedance curve, Fitch summed the product of the probability of loss and the severity of loss to approximate the cumulative expected losses to bond principal from event occurrences within the relevant range. The probability of loss and expected loss of principal were then compared to default frequencies and cumulative expected losses for corporate bonds to assign a base rating range to the transaction. The box on page 7 outlines the mechanics used by Fitch to determine expected loss.

In addition to computing a new exceedance curve, Fitch also implicitly reset the attachment point for its rating analysis from $1 billion to approximately $840 million, based on USAA's book of business. Fitch further stress tested the performance of the bonds by measuring the sensitivity of loss estimates from the model at attachment points ranging from $815 million to $1 billion. The slope of the exceedance curve and, thus, the corresponding frequency and expected loss, will change based on the assumed attachment point. The table below left illustrates the frequency and expected loss probabilities associated with Fitch's rating case, as well as sensitivities at various attachment points.

At the $840 million attachment point, the probability of loss for Fitch's rating case was 2.21%, compared to 1.32% for the base case. The cumulative expected loss for the rating case was 1.35%, compared to 0.83% for the base case. To determine its final rating on the notes, Fitch compared the probability of loss and cumulative expected loss to corresponding probabilities of loss on corporate bonds.

Based on the quantitative analysis of the catastrophic event model, the adjustments made to distribution assumptions, sample size, and vulnerability estimates, and the adjustment made to the attachment point based on review of the insurance data, Fitch concluded that the at-risk portion of the bonds fell within a range of 'BB–' to 'BB+'. The final rating of 'BB' was assigned based on this quantitative analysis, USAA's strong underwriting practices and hurricane claims procedures, and a viable

bond structure (as outlined in the following section).

■ *Transaction Structure*

Residential Re is a single purpose, licensed Cayman Islands reinsurance company whose sole business will be the issuance of $476.98 million of variable-rate notes and the performance under, and activities related to, the reinsurance contract with USAA and related agreements. Approximately $400 million of the note proceeds will be available to USAA as reinsurance coverage in the event of a loss occurrence. The remaining $77 million will be placed in a collateral account as defined in this section. The risk capital portion of the notes provides reinsurance for the risk tier between $1.0 billion and $1.5 billion. USAA is required to maintain a minimum 20% risk participation (or $100 million) in this $500 million tier.

The risk capital provided by the notes (approximately 53% of class A-1 and 100% of class A-2) has been placed in a Regulation 114 trust and invested in commercial paper, with Bankers Trust Co. as trustee. The remaining class A-1 proceeds (approximately $77 million) were placed in a segregated collateral account, which is also invested in commercial paper and managed by Chase Manhattan Bank as indenture trustee. Earnings on commercial paper investments from both accounts will be swapped into one-month London Interbank Offered Rate-based rates under swap agreements with Merrill Lynch Capital Services, Inc.

In the event of a loss occurrence, funds in the collateral account will be available to purchase U.S. Treasury strips with a minimum 10-year maturity value equal to the class A-1 principal amount of $163.8 million. Sufficiency of the funds to purchase these defeasance securities will be ensured through a contingent defeasance securities purchase agreement with Goldman Sachs Mitsui Marine Derivative Products, L.P.

Interest payments to noteholders will be funded through monthly premium payments made by USAA, investment earnings on the trust assets, and swap revenues, which will be deposited into a segregated account (the general account) and will not be available to USAA in an event of loss occurrence. The general account will be managed by Chase.

In the absence of a loss occurrence, principal on both classes will be repaid at maturity. In the event of a loss occ rence, partial or total interest and pr cipal on the class A-2 notes will canceled to the extent of the pro r loss paid, interest on the class A-1 no will discontinue, and principal on cl A-1 will be repaid on maturity of t defeasance securities.

If a loss claim is filed, risk capital will drawn pro rata, according to each se rity's relative percentage investment the Regulation 114 trust. Since the r capital equates to approximately 80% the reinsured risk tier, the noteholde will be required to fund approximat $0.80 of each $1.00 loss claimed. USA will be required to pay an additional or time extension premium with the pr entation of the loss claim. The tal above left approximates draws under t at-risk capital of classes A-1 and A-2 various loss levels.

Scheduled maturity for classes A-1 a A-2 will be on June 15, 1998, appro mately one year from the closing da of June 16, 1997. USAA maintains t option to extend the term through De 15, 1998 to accommodate a loss cla filed after April 1998. Irrespective the extension option, any loss occu rence for which a claim is filed mu occur prior to the scheduled maturi The final maturity date on class A-1 w be the earlier of the maturity of the d feasance securities and Dec. 15, 2008.

Fitch reviewed the legal document tion and legal opinions related to th structure and found them to accurate represent the transaction as presente

Statewide Rate Level Effect

Policy	Total Amount of Insurance (in 000s) ($)	Earned House Years	Earned Premium @ Current Rate Level ($)	Current % Change (%)
HO-6	$2,273,028.00	67,704.62	$90,635,568.67	53.5
Total:	$2,273,028.00	67,704.62	$90,635,568.67	53.5

Program	Policy/Coverage	Do you offer this?
CKI Condo	HO-6	Yes

Rating Example Description	Identical Risk (Yes or No)
Condominium unit in a masonry building with six units; Contents insured for replacement cost at $50,000 with a single $500 deductible for all Section I perils combined; Loss of use insured at 40% of the amount of insurance on the contents; $100,000 Liability coverage; $1,000 Medical expenses; I.S.O. Protection Class 4; I.S.O. HO-6 POLICY TYPE. The rates should be ANNUAL RATES for NEW BUSINESS for a 40 YEAR OLD INSURED with NO CLAIMS IN THE PAST 3 YEARS and NEUTRAL CREDIT. The structure was built in 2005 and does NOT have a hip roof. Sinkhole coverage is included with a $500 deductible. Screened enclosure and mold coverage are excluded. (If screened enclosure or mold coverage cannot be excluded, it should be noted under Risk Difference that the coverage is included and the associated limit provided.) The ONLY recoupment that should be included in the rate is the Florida Hurricane Catastrophe Fund reimbursement premium recoupment, if applicable.	Yes

Program	Policy/Coverage	Do you offer this?
CKI Condo	HO-6	Yes

Rating Example Description	Identical Risk (Yes or No)
Condominium unit in a masonry building with six units; Contents insured for replacement cost at $50,000 with a single $500 deductible for all Section I perils combined; Loss of use insured at 40% of the amount of insurance on the contents; $100,000 Liability coverage; $1,000 Medical expenses; I.S.O. Protection Class 4; I.S.O. HO-6 POLICY TYPE. The rates should be ANNUAL RATES for NEW BUSINESS for a 40 YEAR OLD INSURED with NO CLAIMS IN THE PAST 3 YEARS and NEUTRAL CREDIT. The structure was built in 1990 and is NOT eligible for any windstorm loss reduction credits. Sinkhole coverage is included with a $500 deductible. Screened enclosure and mold coverage are excluded. (If screened enclosure or mold coverage cannot be excluded, it should be noted under Risk Difference that the coverage is included and the associated limit provided.) The ONLY recoupment that should be included in the rate is the Florida Hurricane Catastrophe Fund reimbursement premium recoupment, if applicable.	Yes

INSURANCE REGULATION FILING SYSTEM (IRFS)
RATE COLLECTION SYSTEM (RCS) VERIFICATION

In addition to the RCS submission, you must also provide the following additional information:

1. **For EACH rating example on the RCS submission, you must provide an exhibit that shows step-by-step how you determined the rate in one territory. This exhibit must reference the applicable manual pages. Provide this exhibit in Excel, showing all formulas used.**

   These exhibits are attached.

2. **If windstorm loss mitigation credits are used in rating (e.g., homeowners, dwelling fire, commercial residential property), provide the support described below. If these credits are not used in rating, skip to item 3.**

   For EACH territory set, you must provide an exhibit that shows for EACH territory how the applicable windstorm loss mitigation credit was determined.

   If you are using the OIR-B1-1699/1700 credits, for each territory state whether the applicable windstorm loss mitigation credit for existing construction was determined using Terrain B or Terrain C. Note that Terrain C should be used for all territories completely contained within Broward, Miami-Dade and Monroe counties. Territories equivalent to Citizens' coastal account territories should also use Terrain C. In general, territories that are completely contained within Terrain C should be considered as being in Terrain C. Territories that contain both Terrain B and Terrain C should be considered as being in Terrain B.

   For new construction in Terrain C, the applicable HVHZ credit should be used if the territory is completely contained within Broward and/or Miami-Dade counties, otherwise the Terrain C credit should be used. For Terrain B territories, use the credit associated with the minimum 2001 FBC Wind Speed zone found in that territory.

   If you are using any other set of credits, provide an explanation as to how the applicable windstorm loss mitigation credit was determined for each territory.

   Exhibit I illustrates how the applicable windstorm loss mitigation credit was determined by territory.

   3. Explain how you calculated the current average annual premiums and the proposed average annual premiums shown on the Rate Level Effect form(s). Provide examples of the calculations and supporting data. Note – if your explanation indicates that you use the percent changes to calculate the proposed average annual premiums, then you must explain how you calculated the percent

changes and provide supporting data for these calculations. Note – your explanation must account for any revisions in base rates or any other rating factors. In addition, it must account for any changes in the amount of coverage you are providing to your insureds. A reduction in coverage is a rate level increase and an increase in coverage is a rate level reduction.

In order to provide data at the required level of detail, the extension of exposures technique was utilized to determine percent changes to average premium at the territorial level.

Castle Key is showing the impact of the rate change on data from the extension of exposure technique, but it has been reweighed to the Earned House Years, Amount of Insurance Years and Trended On-Level Earned Premium of the Standardized Rate Level Indication Workbook and Supporting Exhibits.

RATING EXAMPLES FOR TERRITORY 32003

CONDOMINIUM ARRAY FACTOR

EXAMPLE #1

UNLESS OTHERWISE NOTED, ROUND TO TEN DECIMAL PLACES AFTER EACH STEP

STEP #			
2A	Condominium Rate Adjustment Factor (CAFP-1)		1.0000
2B	Construction Type (CAFP-1)	x	0.9008
2C	Rating Group (CAFP-1)	x	1.0000
2D	Number of Fire (Group D) Claims in the past 3 years (CAFP-2)	x	1.0000
2E	Number of Theft/Liability (Group E) Claims in the past 3 years (CAFP-2)	x	1.0000
2F	Number of All Other (Group F) Claims in the past 3 years (CAFP-2)	x	1.0000
2G	Number of Water (Group G) Claims in the past 3 years (CAFP-2)	x	1.0000
2H	Age of Condominium (CAFP-3 to CAFP-4)	x	0.9428
2I	Residence Class Factor by Number of Weeks Rented (CAFP-5)	x	1.0000
2J	Condominium Floor Rating (CAFP-6)	x	1.0000
2K	Square Footage (CAFP-6)	x	1.0000
2Q	Canine Factor (CAFP-7)	x	1.0000
2R	Roof Shape (CAFP-7)	x	1.0000
2S	Condominium Type Factor (CAFP-7)	x	1.0000
2T	Number of Occupants (CAFP-8)	x	1.0000
2U	Number of Bathrooms (CAFP-8)	x	1.0000
2V	Territorial Zone (CAFP-9 to CAFP-13)	x	1.0000
2W	**Total Condominium Array Factor (Round to four decimal places)**	=	**0.8493**

EXAMPLE #2

UNLESS OTHERWISE NOTED, ROUND TO TEN DECIMAL PLACES AFTER EACH STEP

STEP #			
2A	Condominium Rate Adjustment Factor (CAFP-1)		1.0000
2B	Construction Type (CAFP-1)	x	0.9008
2C	Rating Group (CAFP-1)	x	1.0000
2D	Number of Fire (Group D) Claims in the past 3 years (CAFP-2)	x	1.0000
2E	Number of Theft/Liability (Group E) Claims in the past 3 years (CAFP-2)	x	1.0000
2F	Number of All Other (Group F) Claims in the past 3 years (CAFP-2)	x	1.0000
2G	Number of Water (Group G) Claims in the past 3 years (CAFP-2)	x	1.0000
2H	Age of Condominium (CAFP-3 to CAFP-4)	x	1.0463
2I	Residence Class Factor by Number of Weeks Rented (CAFP-5)	x	1.0000
2J	Condominium Floor Rating (CAFP-6)	x	1.0000
2K	Square Footage (CAFP-6)	x	1.0000
2Q	Canine Factor (CAFP-7)	x	1.0000
2R	Roof Shape (CAFP-7)	x	1.0000
2S	Condominium Type Factor (CAFP-7)	x	1.0000
2T	Number of Occupants (CAFP-8)	x	1.0000
2U	Number of Bathrooms (CAFP-8)	x	1.0000
2V	Territorial Zone (CAFP-9 to CAFP-13)	x	1.0000

CASTLE KEY INDEMNITY COMPANY
CONDOMINIUM (HO-6)

CRITERIA FOR DETERMINING WINDSTORM LOSS MITIGATION RATING

Criteria Name	Criteria	Hurricane Factor
A	Group 1, FBC 2001 Construction, Other Roof Deck, HVHZ Terrain Exposure, Opening Protection, Flat Roof Shape with No Secondary Water Resistance	0.15
B	Group 1, FBC 2001 Construction, Other Roof Deck, Terrain Exposure C, No Opening Protection, Flat Roof Shape with No Secondary Water Resistance	0.17
C	Group 1, FBC 2001 Construction, Other Roof Deck, Terrain Exposure B, Gust Wind Speed of Location 100 MPH, Gust Wind Speed of Design 100 MPH, No Opening Protection, Flat Roof Shape with No Secondary Water Resistance	0.24
D	Not eligible for Windstorm Loss Reduction Credit	1.00

RATING FACTOR CHANGES
EXPLANATORY MEMORANDUM

BASE RATES

With this filing, Castle Key is proposing revisions to the Non-Hurricane and Hurricane Base Rates in order to accomplish an overall 53.5% rate level increase.

Using an extension of exposures method, each policy's Non-Hurricane Base Premium is calculated using the proposed Non-Hurricane Territory Relativities. The Non-Hurricane Base Rate is then adjusted to achieve the target increase to the Non-Hurricane Base Premium.

Using the same extension of exposures method, each policy's Hurricane Base Premium is calculated using the proposed Hurricane Territory Relativities. The Hurricane Base Rate is then adjusted to achieve the target increase to the Hurricane Base Premium.

All policies that will be non-renewed have been removed from the extension of exposures measurement.

The current and proposed Base Rates are listed below.

	Current	**Proposed**
Non-Hurricane Base Rate	$1,059.85	$1,614.72
Hurricane Base Rate	$146.81	$248.86

COVERAGE A – BUILDING PROPERTY PROTECTION

An insured has the option to purchase more or less coverage for Coverage A - Building Property Protection than is included in the base policy for an additional charge or reduction in premium. This coverage is provided at a percent of the Coverage C limit. The base policy for CKI includes Coverage A at 30% of Coverage C.

Hurricane and Non-Hurricane Rates

With this filing, Castle Key is proposing revisions to the Non-Hurricane and Hurricane Coverage A Rates Per $1,000 in order to accomplish an overall 53.5% rate level increase. Each policy's Hurricane and Non-Hurricane Coverage A Premium is calculated using the new territorial relativities. The Non-Hurricane Coverage A Rates are then uniformly adjusted by an offset factor to achieve the target increase to the Non-Hurricane Coverage A Premium, and the Hurricane Coverage A Rates are similarly adjusted by an offset factor to achieve the target increase to the Hurricane Coverage A Premium.

The derivation of the proposed Coverage A rates is shown in **Territory Support Exhibits 3.1, 3.2, 4.1, and 4.2**.

* Each credit must be listed as the percentage of the total premium that is eliminated when wind/hail coverage is excluded (i.e. if 60% of the total premium is eliminated, the credit must be listed as 60.0). In the "Notes" below, include an explanation of the determination of the lowest, highest, and estimated average credits. If the line of business is Dwelling Fire, indicate whether the credit is to be applied to the Extended Coverage portion of the premium or the total Fire and Extended Coverage premium in the "Notes" below.

NOTE: See CITIZENS web site at "www.CitizensFla.com" for detailed wind-only territory definitions.

NOTE: Ten exhibits are included. If more are required, additional worksheets may be added and the exhibit may be copied to these worksheets.

Notes:

The credits displayed were calculated by comparing the base premium and additional coverages premium charged to customers with wind coverage, to the estimated premium the customers would be charged if they had the Windstorm or Hail Exclusion endorsement. The calculations were performed at a policy level to determine the maximum and minimum credits. The average credit is calculated at the county level. Counties without any exposures did not have premium data to calculate credits for and are listed as 0.

CASTLE KEY INDEMNITY COMPANY
FLORIDA
CONDOMINIUM

ALL INPUT MODEL DATA MEMO

The data used to develop the model has previously been submitted with filing FCP 10-10281. It is our understanding that an additional copy is not necessary.

CREDIT REPORTS / INSURANCE SCORES

Questionnaire A - Use of Credit

You have answered "YES" to the question "Does your company(ies) use credit information, credit reports, or credit/insurance scores in underwriting or rating (including any categorization that would affect the premium charged to your insureds or prospective insureds)?"

Therefore you must provide the following (Note: Any material omission may result in disapproval of your filing):

1. Information concerning the use of credit reports and credit scores. Provide:

   (a) A listing of the types of individuals whose credit reports or scores the company will use or attempt to use to underwrite or rate a given policy. (For example: Person signing application, named insured, all listed operators)

   For any one policy, credit reports will be ordered for the named insured and for the spouse (if any) of the named insured.

   (b) If more than one credit report or score may be used on a policy, an explanation of how they will be combined. (For example: average score or highest score)

   The insurance scores will be averaged to determine the policy insurance score unless one of the insureds that a credit report was requested for was not obtainable or consisted only of inquiries. In this case, only the credit report that was obtainable will be used to determine the score for the policy.

   (c) The name(s) of the consumer credit reporting agencies or any other third party vendors from which the company will obtain or attempt to obtain credit reports or scores.

   Credit reports are obtained from TransUnion.

   (d) Precise identifying information specifying or describing the credit scoring methodology (if any) the company will use. Include common or trade name, version, subtype or intended segment of business the system was designed for, and any other information needed to distinguish a particular credit scoring methodology from other similar ones, whether developed by the company or by a third party vendor.

   For Castle Key Indemnity Company, we use an insurance scoring model referred to as ISM7. This model is a proprietary insurance scoring model, which has been developed by Allstate Insurance Company.

(e) The effect of particular items appearing on a credit report (if no scores are used) or particular scores or ranges of scores on:

(1) the insurance rate, or

The rate charged will vary depending on the insurance score assigned to the policy.

(2) placement in rating tier, or

Placement in a rating tier will vary depending on the insurance score assigned to the policy.

(3) placement in company within an affiliated group of insurance companies, or

There is no effect.

(4) decisions concerning issuance, renewal, exclusions, restrictions or payment plan on a policy of insurance

Please see the most recent underwriting guidelines filed on behalf of Castle Key Indemnity Company for additional details.

(f) The effect of the absence of or insufficiency of credit history on any items listed under (e) above.

For those policies where one credit report was obtainable and the other credit report was absent or had insufficient history, the absent or insufficient credit report will not be used in rating the policy. For policies where no credit report is obtainable or all credit reports have insufficient history, a specified insurance score will be assigned to the policy which affects the rate charged and the placement of the policy in a rating tier.

(g) The list of all clear and specific primary reasons that can possibly be cited to the consumer as the basis or explanation for an adverse decision. Describe the circumstances under which each of those reasons will be shown on a notification to a consumer.

When Castle Key's insurance scoring model calculates a score that does not fall into the range of scores corresponding to the most favorable group, it also calculates the primary reasons why the score was not in the very best group. This is done separately for each policy by comparing the points assigned to each specific variable in the model to the number of points that are assigned to those who fall into the very best group of scores. The difference is then used to rank each variable in the order that it contributed to a higher score. Up to four reasons are recorded; however, only those variables for which the consumer's assigned points exceeded the average points of those in the best group would be considered as a potential reason.

For each specific variable a reason may be generated. These reasons will include specific information such as

- **The presence of a collection within the past five years: When we refer to a "collection", this could include collections that were previously paid off or collections on closed accounts. We exclude medical collections that are identified as such. Those with the most favorable insurance scores will typically have no collections on their credit report. Avoiding future collections may lead to a more favorable insurance score.**

We have examined standardized credit explanations provided by other modelers, including a consumer reporting agency and a third-party modeler, and have found that our reasons provide similar information or more information than the reasons used by these other modelers.

Please see pages 16-18 of the attached Insurance Scoring Model 7 (ISM7) document included with this filing for a listing of adverse action reasons.

(h) Does your company correct any error in premium charged the insured or underwriting decision made concerning the insured, if the basis of the premium charged or decision made is a disputed item that is later removed from the credit report?

Yes.

2. Insurers desiring to make adverse decisions concerning consumers or applicants with an absence of or an insufficiency of credit history -- Provide the following to establish that the absence or insufficiency is sufficiently related to the risk assumed by the insurer to warrant the treatment proposed by the company.

(a) Data comparing experience for those with absent or insufficient credit to each category of insureds separately treated with respect to credit and having sufficient credit history.

Not applicable.

(b) A valid method of analysis that concludes that there is high probability that the relationship between absence or insufficiency of credit history and the risk assumed is not due to chance

Not applicable.

(c) A valid method of analysis that confirms that the treatment proposed by the company is quantitatively appropriate

Not applicable.

(d) Statistical tests establishing that the treatment proposed by the company is warranted for at least two identifiable subgroups of, as well as for the totality of, consumers with absence or insufficiency of credit history

Not applicable.

Please double click on the applicable box to answer.

YES	NO	
☒	☐	1. Do you have written procedures to inform applicants or insureds, in the same medium that an application is taken, that a credit report or score is being requested for underwriting or rating purposes?
☒	☐	2. Do you have written procedures providing for notification to a consumer when an adverse decision is taken concerning that consumer, explaining the four primary reasons (or such fewer number as existed) that were the primary influences on your adverse decision?
☒	☐	3. Do you have written procedures prohibiting a request for a credit report or score based upon the race, color, religion, marital status, age, gender, income, national origin, or place of residence of the applicant or insured?
☒	☐	4. Do you have written procedures prohibiting an adverse decision solely because of information contained in a credit report or score?
☒	☐	5. Do you have written procedures prohibiting adverse decisions based in whole or in part on the absence or insufficiency of credit history? This means that you treat the consumer as if he or she had neutral credit information or exclude the use of credit information for such consumers. Should you desire OIR approval to do otherwise, submit information demonstrating that the absence or insufficiency is related to the risk assumed.
☒	☐	6. Do you have written procedures prohibiting adverse decisions based in whole or in part on collection accounts with a medical industry code (if so identified on the consumer's credit report) or based upon place of residence?
☒	☐	7. Do you have written procedures prohibiting the use of credit inquiries not initiated by the consumer?
☒	☐	8. Do you have written procedures prohibiting the use of credit inquiries by the consumer for his or her own credit information?
☒	☐	9. Do you have written procedures prohibiting the use of credit inquiries relating to insurance coverage (if so identified on a consumer's credit report)?
☒	☐	10. Do you have written procedures prohibiting the use of collection accounts with a medical industry code (if so identified on the consumer's credit report)?
☒	☐	11. Do you have written procedures prohibiting the use of multiple lender inquiries from the home mortgage industry or the automobile lending industry (if coded by the consumer reporting agency on the consumer's credit report) made within 30 days of one another, unless only one inquiry is considered?
☐	☐	12. If you purchase a credit score from a vendor (such as Fair, Isaac or Choicepoint), does that vendor have written procedures in place prohibiting the use of the preceeding five (5) items?
☒	☐	13. Have you evaluated your use of credit reports and credit scores in underwriting and rating and concluded that the resulting rates are not excessive, inadequate, or unfairly discriminatory?
☒	☐	14. Do you have written procedures in place providing a means of appeal for an insured or applicant whose credit report or credit score is unduly influenced by dissolution of marriage, the death of a spouse, or temporary loss of employment?
☒	☐	15. Do you have written procedures that reflect the restrictions set forth in the federal Fair Credit Reporting Act and s. 626.9741. F.S?
☒	☐	16. Do you have written procedures to review the credit history of an insured who was adversely affected by the use of credit history at the initial rating of the policy or subsequent renewal thereof at least once every 2 years or at the request of the insured, whichever is sooner and to adjust the premium of the insured to reflect any improvement in the credit history?
☐	☐	17. If the answer to the prior question is "no", do you have written procedures that prohibit the use of a credit report or score for reunderwriting and that provide for a reevaluation of insureds within the first 3 years after inception, not increasing rates charged to the insured based on the exclusion of credit reports or scores?
☒	☐	18. Do you have written procedures that prohibit canceling, refusing to renew, or requiring a change in the method of payment or payment plan with respect to existing policyholders as a result of the review of credit history?

☐	☒	19. Have you undertaken a review of your use of credit reports or scores to determine whether the rates or premiums associated with that use are unfairly discriminatory based upon race, color, religion, marital status, age, gender, income, national origin, or place of residence?

INSURANCE REGULATION FILING SYSTEM (IRFS) -- CREDIT REPORTS / INSURANCE SCORES

Questionnaire B – Development and Use of Insurance Scores in Connection with Premiums Charged by Insurers

You have answered "YES" to the question "Does your use of credit reports / insurance scores affect the premium that your insureds or prospective insureds are charged?"

Therefore you must provide the following (Note: Any material omission may result in disapproval of your filing):

1. In the event an adverse decision (as defined in Section 626.9741(2)(a), Florida Statutes) is made, is an insured or applicant provided, at no charge, with a copy of the credit report, or the name, address, and telephone number of the consumer reporting agency from which the consumer may obtain the credit report?

   Yes, the insured or applicant is provided with the name, address, and phone number of the consumer reporting agency from which they may obtain their credit report at no charge.

2. A conclusive demonstration that any credit scoring methodology or ranking or grading method used with credit report data is a valid predictor of the insurance risk to be assumed by the insurer for the applicable type of insurance. Note that the fact that a third party performed any or all of the analysis does not excuse the filer from providing the required information. The demonstration shall include the following:

   (a) A listing of all persons who contributed substantially to the development of the method, including resumes of such persons (unless unobtainable) indicating their qualifications and experience in similar endeavors.

   The following is a list of persons who contributed substantially to the development and validation of Castle Key's ISM7 model. Andy Lau, Charity Cummings, Patrick Causgrove, Christine King, Grace Zakaria, Mary Schreck, Keith Krostal, Dean Lamb and Peggy Brinkmann. All of these people have multiple years of insurance research experience, and several have been involved in the development of other insurance scoring models. In addition three of these individuals currently hold the designation of FCAS from the Casualty Actuarial Society.

   (b) An enumeration of all data cleansing techniques (correction or enhancement of presumed incomplete, incorrect, missing, or improperly formatted information) that have been used in the development of the methodology. This must contain the nature of each technique, any biases it might introduce, and the prevalence of each type of invalid information prior to correction or enhancement.

   We have provided a document along with this filing entitled Model Development Overview & Final Model Results. This document provides

an overview of the methodology used to develop this specific model. Pages 8 & 9 of this document contain specific information with respect to data adjustment techniques applied to the data used for model development. The first is the exclusion of records for which our outside vendor could not find matching credit information. Since our algorithm is designed to use the credit report variables as independent variables for consideration in a predictive model, records for which no credit information is available are not suitable for model building. We believe the exclusion of these records will not introduce any significant bias as the remaining records are representative of those whose credit reports will be scored by our insurance scoring model in the course of business. In addition, we have also removed all losses related to catastrophes from the data used to develop our scoring algorithm. This will minimize the chance that significant catastrophe related events could have undue influence on the selection of variables and the associated weights used in the scoring algorithm.

(c) All data input that was used by the model developers in the latest validation of the model parameters. Data shall be in sufficient detail to permit the Office to conduct multiple regression testing for credit scoring methodology validation and shall be supplied in electronic format. Field definitions must be included.

The ISM7 model was developed using policyholder data from exposure years 2001 and 2002 from the majority of states across the country. Exposures and losses for exposure years 2001 and 2002 were combined using new and renewal business in 2001 and only renewal business in 2002. The model was then tested against a holdout sample, which included information from over 1 million automobile policies and also over 1.6 million homeowner policies. Exhibits 3-7 of the Model Development Overview & Final Model Results, provide detailed results of the validation testing. The data used to develop the model has previously been submitted with filing FCP 10-10281. It is our understanding that an additional copy is not necessary.

(d) Statistical results showing that the model and parameters are statistically significant and not overlapping or duplicative of any other variables used to rate an applicant. These results shall include the length of time for which each element from a credit report is used.

Pages 9, 19 & 20 of the document entitled Model Development Overview & Final Model Results provide information to show that the model and parameters are statistically significant and not overlapping or duplicative of any other variables used to rate an applicant.

With respect to the length of time that the various elements of the credit report are used, the following is taken from the document entitled Model Development Overview & Final Model Results. All variables except Inquiry variables were computed using a 5-year window ending with the date of the credit snapshot. For trade accounts, if the trade account has a

verified, closed, or paid date within 5 years from the credit snapshot date, then it has satisfied the 5-year window screening. For public records and collections, the 5-year window is computed using the difference of report date and credit snapshot date. Inquiry variables are computed using only a 2-year window (using inquiry date).

(e) A precise listing of all elements from a credit report that are used in scoring and the formula used to compute the score. The listing shall include the length of time for which each element is used.

A precise listing of all the elements from a credit report that are used in scoring and the formula used to compute the score are included in the document entitled Model Development Overview & Final Model Results on pages 3-7. Unless otherwise noted, all variables except Inquiry variables were computed using a 5-year window ending with the date of the credit snapshot. Inquiry variables are computed using only a 2-year window (using inquiry date).

(f) Company insurance data for the applicable Florida program, policy, or coverage that validates the premium differentials proposed based on the scores or ranges of scores. Industry or countrywide data may be used to the extent that the Florida company data lacks credibility. Claims on property insurance policies that are the result of acts of God shall not be included in the validation data.

Support for the previous revision of Rating Group Factors was provided in filing FCP 19-124744. No further changes are being proposed with this filing.

(g) The credibility standards and any judgmental adjustments (including limitations on effects) that have been used in the process of deriving premium differentials proposed and validated in (i) above.

Support for the previous revision of Rating Group Factors was provided in filing FCP 19-124744. No further changes are being proposed with this filing.

(h) The date that each of the analyses, tests, and validations required in (d) through (g) above was most recently performed and a certification that the results continue to be applicable.

Analyses, tests and validations required in (d) through (e) above were all performed in 2004 or later. In addition, validation data from 2017-2019 which continues to show that ISM7 remains a valid predictor of insurance risk is included along with the Model Development Results as Exhibit HO-20. The loss experience under ISM7 will be monitored going forward and be adjusted as appropriate with future filings.

3. A certification that no use of credit reports or scores in rating insurance will apply to any component of a rate or premium attributed to hurricane coverage for residential properties as required by Section 627.0629, F.S.

   We certify that no use of credit reports or scores in rating insurance will apply to any component of a rate or premium attributed to hurricane coverage for residential properties as required by Section 627.0629, F.S.

Allstate Insurance Company

Insurance Scoring Model 7

Model Development Overview & Final Model Results

Model Overview

Allstate has been studying the relationship between credit report information and insurance loss potential since the 1980's. In 2000, Allstate introduced its first insurance scoring model, a proprietary scoring model developed internally by Allstate using information from our policyholder records, combined with credit report information obtained for research purposes. Since that time, Allstate has continued to evaluate the predictive power of credit information, and has developed additional insurance scoring models. This report contains information on the development of the insurance scoring model referred to as **Insurance Scoring Model 7 (ISM7).**

In the development and validation of this insurance scoring model, we leveraged data from the majority of states, using over 10 million automobile and homeowners policies. While we have reviewed information separately for the automobile and homeowners lines of business, the ISM7 model was designed with the goal of creating a single model that would accurately predict insurance loss potential for both automobile and homeowners insurance.

Since 2002, many states have passed laws and regulations regarding the use of credit information for evaluating insurance risks. While many of the variables prohibited by these laws and regulations have never been considered in any of our insurance scoring models, others have led to the creation of state specific models to address specific prohibitions. The ISM7 model has been created to address most of the common prohibitions so that this model can be utilized without modification in as many states as possible.

Insurance scoring is just one of many rating variables considered by Allstate in determining insurance premiums. As such, we have developed our insurance scoring model to capture the additional predictive power that credit information provides above and beyond what the other rating variables already predict.

The ISM7 Model was designed to predict the likelihood of insurance losses. The scoring model was developed using a multiple regression technique that simultaneously solves for the weights of all credit report variables utilized in the model. The ISM7 Model was constructed so that a lower risk of loss would be associated with a lower overall score as generated by the insurance scoring model. Higher scores are associated with a higher risk of insurance loss. Thus credit report attributes that are more favorable will result in a reduction of points, or the assignment of fewer points than credit report attributes that are considered less favorable.

ISM7 Scorecard

The ISM7 score will be calculated by adding or subtracting points based upon the table below. The initial starting value for the score calculation is 451.17. The final score will rounded to the nearest whole integer.

Variable	Point Value
Presence of derogatory item in the past 5 years (other than one 30-day late payment)	18.35
Presence of a severely derogatory trade in the past 5 years	18.13

Months since the most recent bank or credit card inquiry	
No of months (capped at 24) multiplied by	-0.7183
(If no bank or credit card inquiries use 24 months)	

Variable Descriptions

A credit report contains different types of information including Inquiries, Public Records, Tradelines and Collections. Inquiries show that credit grantors or other authorized parties have received a copy of the consumer's credit report. Public Records includes items such as liens, court judgments, foreclosures and bankruptcies. A tradeline is a broad term including all types of credit accounts a consumer has on their credit report, which may include several different types of trade accounts such as mortgages, installment accounts, lines of credit, open or revolving accounts. In addition, items that are unpaid and are sent to collection can result in a collection record appearing on the credit report. Each of these types of information, found on a credit report, are considered in the calculation of an insurance score.

The credit variables utilized in the ISM7 Model can be categorized into five general categories: Performance on Accounts and Public Records, Number of Accounts, Utilization of Accounts, Length of Account History, and Credit Seeking Behavior as measured by Inquiry Information.

While some derogatory credit report information may remain on a credit report for seven years or more, the variables utilized in the ISM7 Model only consider information from the past five years (with the exception of the average length of time trade accounts have been on the file). Inquiry information is only available for the latest two years.

Certain information will specifically be excluded from consideration including:

- Items that are indicated to be in dispute
- Items designated as being medically related
- Accounts coded as being business, commercial, utility, insurance or employment related
- Accounts indicating the consumer is a co-signer but does not have primary responsibility
- Accounts designated as being related to spouse, family or child support
- Accounts indicated as credit cards that have been lost or stolen
- Accounts indicating the ownership of the account is in dispute

Delinquencies on accounts are considered for trade items related to cellular phones or student loans; however, these accounts are not considered in evaluating the number of trade accounts, the age of accounts or the number of accounts recently opened.

Performance on Accounts and Public Records

Presence of a derogatory item in the past 5 years (other than one 30-day late payment)

This variable considers the presence of collection records, public records and Tradeline items indicating the presence of a delinquency, bankruptcy, judgment, lien, repossession or a foreclosure. If only one delinquency, coded as 30-days late, is present on the credit

report and no other derogatory items are found, then no points will be assigned for this variable.

Presence of a severely derogatory trade in the past 5 years
This variable considers the presence of severe delinquencies on accounts. In order to be considered severely derogatory, a delinquency must be beyond 120 days late, which would include accounts that are sent to collection, repossessed, charged off as a bad debt or subject to a wage earner plan.

Number of collections in the past 5 years
This variable counts the number of collection records during the past 5 years. Collection records that are indicated as medically related are excluded from consideration.

Revolving trades currently 60-120 days past due
This variable only considers delinquencies on revolving trade accounts. The account must indicate a current delinquency of 60, 90 or 120 days to be considered.

Number of payments 30 days late in the past year
This variable counts the number of 30-day late payments, across all trade accounts, occurring within the past 12 months. Current 30-day late payments as well as historical 30-day late payments will both be considered. At most one 30-day late payment will be counted from each trade account.

Months since the most recent delinquency
In addition to considering the presence of delinquencies, we also consider how recently those delinquencies have occurred. The farther back in time delinquencies appear, the less of a negative impact they will have on the insurance score. Those with no delinquencies in the past 60 months will receive the maximum reduction in points associated with this variable.

Number of derogatory public records in the past 5 years
Derogatory public records reported within the past five years are considered.

Months since the most recent derogatory public record
In addition to considering the presence of derogatory public records, additional points will be assigned if a derogatory public record item has been reported within the past 4 months.

Amount currently past due
For this variable, the balance currently past due is accumulated on all open trade accounts.

Number of Accounts

Number of trades in the past 5 years
This variable considers the number of trade accounts held during the past 5 years. A trade account will be considered regardless of whether the trade account is currently opened or has been closed. Those with either very few accounts or with a very large number of accounts will see points added to their score.

Utilization of Accounts Credit

Number of open revolving trades > 75% of high credit amount
This variable looks at the current balance on each open revolving account, in relation to the highest balance ever accumulated on that account (accounts designated as a line of credit or an open account type are also considered for purposes of this variable). We do not consider the absolute balance of the account separately, but only as a ratio to the high credit amount. In addition, if the high credit amount for a particular trade account is less than $500 then a high credit amount of $500 is used. No points are assigned under this variable unless there are at least two open revolving accounts with a balance > 75% of the high credit amount.

Percent of active trades with a positive balance
This variable considers the number of open trade accounts that have been reported on in the past year and that have a balance greater than zero. The percentage of accounts is then calculated and multiplied by a factor 100 (rounded to the nearest integer). This variable is only considered in combination with the number of **Credit card inquiries**.

Length of Account History

Average number of months trades on file (excluding auto and mortgage related trades)
This variable considers the number of months between the date each trade account was opened and the date the credit report is reviewed. If the date an account was opened was over five years ago, or if an account has been closed for more than five years, these accounts will still be considered in the calculation of this variable; however, auto and mortgage accounts are not considered in the calculation of this variable. The longer the average length of time that trade accounts have been opened, the more points are deducted from the score.

Revolving trades opened in the past 2 years (excluding auto and mortgage related trades)
This variable considers only revolving trades that have been opened in the past 2 years. If an account is currently closed it will still be considered in the calculation of this variable. Auto and mortgage accounts are excluded from consideration.

Installment trades opened in the past 2 years (excluding auto and mortgage related trades)
This variable considers only installment trades that have been opened in the past 2 years. If an account is currently closed it will still be considered in the calculation of this variable. Auto and mortgage accounts are excluded from consideration.

Credit Seeking Behavior - Inquiry Information

Number of bank inquiries in the past 2 years (considers no more than one bank inquiry within a 90-day period)
This variable only considers inquiries that are coded as bank inquiries. In addition, inquiries are grouped into three-month intervals for the 24 months of inquiry information available on the credit report. For each three-month time period, beginning with the most recent three months, at most one bank inquiry will be considered. In calculating the total number of bank inquiries to consider, each three-month interval is searched for the presence of a bank inquiry. If a bank inquiry is present, one inquiry is added to the count, and the next three-month interval is skipped from consideration. The entire 24-month history is searched in the same manner. As a result of the way in which this variable is calculated, at most 4 bank inquiries will be considered, and all bank inquiries considered will be a minimum of 90 days apart.

Number of credit card inquiries in the past 2 years
This variable considers only inquiries that are coded as credit card inquiries. Department Store inquiries are coded separately on a credit report, and are not included in the calculation of this variable. The points assigned for this variable will vary based upon the calculation of the **Percent of active trades with a positive balance**. The presence of credit card inquiries results in additional points being added to the score. However, fewer points will be added in cases where the percentage of active trades currently carrying a positive balance is smaller.

Months since the most recent bank or credit card inquiry
In addition to considering the presence of bank and credit card inquiries, we also consider how recently those inquiries have occurred. The farther back in time inquiries appear, the less of a negative impact they will have on the insurance score. Those with no bank or credit card inquiries in the past 24 months will receive the maximum reduction in points associated with this variable.

Data and Data Adjustments

In the development of the ISM7 Model, we relied upon policyholder data from exposure years 2001 and 2002 from the majority of states across the country. Exposures and losses for exposure years 2001 and 2002 were combined using new and renewal business in 2001 and only renewal business in 2002. For standard private passenger automobile, we used data for the Bodily Injury, Property Damage, Collision and Comprehensive coverages. The data file we relied upon for analysis purposes is referred to as the Policy History File. Each policy was then matched with a raw credit report snapshot from December of 2000, obtained on a blinded basis. All policyholder identifying information was removed from both the credit report information as well as Allstate's Policy History File.

Credit information was summarized on an individual level, and then one report per policy was randomly selected between the named insured and the spouse, if applicable, on the policy. Since our algorithm is designed to use credit report attributes as independent variables for consideration in a predictive model, records for which no credit information was available were not suitable for model building. For standard private passenger automobile, the percentage of records for which the credit report vendor could not find matching credit information was approximately 25%. For homeowners, the percentage was approximately 17%. We believe the exclusion of these records will not introduce any significant bias, as the remaining records are representative of those whose credit reports will be scored by our insurance scoring model in the normal course of business.

In June of 2004, a change was brought about by the passage of the federal FACT Act, which limited the ability of credit reporting agencies to report medically related information to third parties. As a result, more information can now be identified as medically related, which is significant because Allstate's insurance scoring algorithms have been created to exclude information that is identified as being medically related. Since the archived credit reports obtained for the purposes of building the ISM7 Model contained credit snapshots from prior to the time this change was made, we adjusted the credit report information to exclude medically related items, so that the credit report information used for model building purposes would be consistent with the information to which the model would be applied prospectively.

In addition, we made the following adjustments to the loss experience data. For homeowners insurance, we removed all losses related to catastrophes from the data used to develop our scoring algorithm. This will minimize the chance that significant catastrophe related events could have undue influence on the selection of variables used in the scoring algorithm. For similar reasons, we also capped any loss amounts more than three times greater than the dwelling coverage limit for the policy. All losses were also adjusted to a common deductible level. For the standard automobile insurance data, any losses were capped at $100,000 in a given year for an individual automobile. This cap was applied to each individual coverage.

Dependent Variable

Our goal in developing this model was to capture the predictive power of credit report variables above and beyond those other factors already known to influence the cost of insurance. Additionally, since Allstate used insurance scoring in its premium determination process in many states during 2001 and 2002, the premiums captured on our analysis files reflect differences in premiums charged to our customers based upon information contained in their credit reports.

To address these two issues, we developed as our dependent variable a theoretical loss ratio, which would account for the effects of other variables, other than those related to credit history. In order to accomplish this we began by using capped pure premium information at the coverage and policy level. We then performed a multivariate analysis, using Bailey's minimum bias procedure, to develop indicated rating factors for the variables other than credit history. The pure premium for each policy was then adjusted based upon these indicated factors. The pure premiums were further adjusted by a theoretical base rate for each respective coverage, allowing the loss experience to be aggregated across all coverages. The end result was a theoretical loss ratio; that is, the loss ratio that would have resulted had credit information not been used and all other plans were reflected in the premium based upon the indicated factors developed from the multivariate analysis. This theoretical loss ratio was used as the dependent variable for purposes of building the ISM7 Model.

In the creation of the ISM7 Model, the private passenger automobile data utilized was randomly divided into three distinct segments. We used 40% of the data to perform the multivariate analysis described above for purposes of developing indicated rating factors used in the creation of the dependent variable (this included information from over 2 million policies). Data from over 2 million policies, or 40% of the data, was used for purposes of building the model, and the remaining 20% of the data was maintained as a holdout sample, so that the model could be validated on a data set independent from the data upon which the model was built. In the creation of the dependent variable, there were various states for which the data was unable to be combined easily into a countrywide analysis, generally as the result of unique rating classifications. As a result, data from CA, HI, MI, NC, NJ and TX were not included.

Over 5 million homeowner policies records were available for analysis. All homeowner policy records were used in the multivariate analysis that determined the dependent variable for the homeowners data. The data was randomly split into a development sample, used in the process of model variable identification, and a holdout sample. The development sample included 2/3 of the data or approximately 3.3 million policy records, while the remaining 1/3 was used as a holdout sample (1.7 million records). For homeowners, the states of CT, ME, NH, NJ, RI, TX and VT were not included in the data used for model building and analysis.

Analysis and Model Building

The ISM7 model was designed with the goal of creating a single model that would accurately predict insurance loss potential for both automobile and homeowners insurance. Initially we began with our standard private passenger automobile data, and several phases of initial exploratory analysis were conducted. The first step of the model building process was to reduce the list of potential candidate variables to a more reasonable, heterogeneous set of predictor variables. This included univariate analyses, to insure that only variables shown to be predictive of insurance losses were being considered as potential candidates for the model. These variables were also carefully studied for potential changes in value over time, and variables which demonstrated a higher level of stability were given preference in the building of the model. Also, a clustering procedure was used to find groups of similar, correlated variables. This procedure finds clusters of variables that are highly correlated with each other and as uncorrelated as possible with variables in other clusters. Based upon the results of this analysis, we judgmentally selected candidate variables that were not highly correlated with one another and which would minimize any estimation problems associated with multicollinearity.

The next step involved a stepwise regression procedure to identify the candidate variables that were most significant in predicting the dependent variable. An additional procedure called CVT (Continuous Variable Transform), which was developed internally at our Allstate Research and Planning Center, was also applied. This technique performs a stepwise, residual based selection, and also optimally forms classification groupings for each variable. This procedure not only aids in the selection of model variables, but also provides information on the optimal classification of each variable's values, and appropriate values for capping.

Once initial model variables were identified based upon a review of our standard private passenger automobile information, a similar process was completed using loss information for our homeowners line of business. In this way the final model variables were defined based upon the analysis of both automobile and homeowners data. All the variables included in the ISM7 Model were found to be statistically significant in the stepwise regression procedure at a significance level of 0.2 for our standard automobile analysis.

In order to allow more flexibility in the model building process, it was decided to use least squares regression to fit the final model. This allowed us to test several combinations of variables along with possible variable interactions. While the parameters of the model were fitted using the private passenger automobile dependent variable data, model results were validated on a holdout sample of information for both standard automobile data as well as homeowners data. Thus several iterations of the model were reviewed in order to identify a final model which would most effectively predict loss experience for both automobile and homeowners data.

Legal Considerations

Over the past few years, various states have passed laws or developed regulations affecting the use of credit information, and many of these laws and regulations have placed restrictions on the use of certain information in the development of insurance scoring models. While there are many unique provisions that vary from state to state, there are some restrictions that are common across several states. Provided below is specific information as to how the ISM7 Model has been designed to assure compliance with some of the more common prohibitions. (Note this is not intended to be a comprehensive list of all prohibitions, and Allstate's models and our procedures in all states are designed to comply with all applicable laws and regulations regarding the use of credit information).

Use of income, gender, address, zip code, ethnic group, race, religion, color, sex, marital status, disability, national origin or ancestry of the consumer

These items are not, nor have they ever been, included in any of Allstate's insurance scoring models and none of these factors were considered in the development of our ISM7 Model.

Items in dispute

A thorough analysis of all remark codes that may appear on a credit report was conducted to identify those that indicate that a particular account is the subject of a dispute. Any items coded as being the subject of a dispute are not considered in the calculation of any derogatory variables. In other words, any item that is coded as being in dispute will not negatively affect the calculation of the insurance score. Other codes, such as those that show a credit card is lost or stolen, or that the ownership of an account is in dispute, are excluded from consideration as well.

Collection accounts with a medical industry code

In determining the number of collections on a credit report, the ISM7 Model will exclude collections that are designated as medically related. A collection item may be designated as medically related in one of two ways. If there is a code that shows the type of loan associated with the collection to be medically related, then this collection will not be considered. In addition, the Collection Agency Name or Creditor's Name field for a particular collection may be returned with the word MEDICAL if our credit report vendor has determined that the information originally contained in these fields was medical in nature. If the word MEDICAL appears in either of these fields for a particular collection account, this collection will not be considered in the calculation of a score.

Additionally, the ISM7 Model not only excludes medically related collection accounts, but any type of account, inquiry or public record that is coded as medically related is excluded from consideration by the model.

Multiple lender inquiries made within thirty days of one another.

Certain state laws require special consideration for multiple lender inquiries from the home mortgage industry or the automobile lending industry, when such inquiries are made within thirty days of one another. The ISM7 model does not consider auto inquiries in the calculation of a score. Bank inquiries are considered as a part of the variable **Number of bank inquiries in the past 2 years**, and bank inquiries are often related to home mortgage accounts. In the calculation of this variable, bank inquiries are grouped by three-month intervals for the 24 months of inquiry information available on the credit report. For each three month time period, beginning with the most recent three months, at most one bank inquiry will be considered. In calculating the total number of bank inquiries to consider, each three-month interval is searched for the presence of a bank inquiry. If a bank inquiry is present, one inquiry is added to the count, and the next three-month interval is skipped from consideration. The entire 24-month history is search in the same manner. As a result of the way in which this variable is calculated, at most four bank inquiries will be considered, and all bank inquiries considered will be a minimum of 90 days apart.

Total available line of credit

The ISM7 Model does not consider the amount of available credit either with respect to a specific trade account or across a group of trade accounts. While we do consider the balance of a particular trade account in the calculation of the **Number of open revolving accounts > 75% of high credit amount**, the balance is only considered as a percentage of the highest balance ever accumulated on that trade account. The balance and the high credit amount are only considered in relationship to one another and are considered as a percentage. Thus, a balance of $500 relative to a high credit amount of $1,000 would be considered the same as a balance of $2,000 relative to a high credit amount of $4,000. The absolute credit limit is not considered in the calculation of this ratio.

Model Results and Validation

The scorecard contained in this package shows the specific variables and the corresponding weights used in the ISM7 model. These weights were taken directly from the multiple regression procedure used to develop the model, and then were multiplied by a factor of 600 so that the score ranges resulting from the application of the model would be similar to those produced by other insurance scoring models we have developed. Our model was constructed so that a lower risk of loss would be associated with a lower overall score, and higher scores are associated with a higher likelihood of insurance losses.

Model Variable Statistics

Exhibits 1a & 1b, show the results from the preliminary stepwise analysis, including the C(p) statistic and significance level of entry for each variable included in our model. A significance level of 0.2 was used to evaluate candidate variables for the model, and all variables included in the ISM7 Model were significant at this level in the standard auto analysis. For the homeowners analysis, the same set of variables typically showed a high level of significance as well (although not all variable were significant at the 0.2 level). As a result, we concluded the set of variables would allow us to create a single insurance scoring model that would allow us to predict loss potential for both automobile and homeowners insurance.

While a specific coefficient is associated with each variable used in our insurance scoring model, these numbers would not be considered as a weight that could be used to determine the "order of importance" of the variables in the insurance scoring model. In fact there is no single agreed on procedure for determining the importance of each model variable. One statistic that can be used to estimate the relative contribution of each variable in the model would be the partial percent contribution, which indicates the extent to which the R-squared in the regression model would decrease if the variable were removed. Larger percentages indicate variables that are statistically significant and contribute strongly to the model even after all other variables are accounted for. The calculation of partial contribution for the variables included in the ISM7 Model is shown on Exhibit 2.

Overall Model Results

Exhibit 3a shows the performance of the ISM7 Model on the standard automobile holdout sample. The policies in this data set were placed in deciles (ten groups of equal size) based upon the score generated by the ISM7 Model. The first decile then represents the 10% portion of the policies with the lowest scores. The validation results clearly demonstrate the ability of the model to segment the population into groups of customers

with distinctly different loss experience based on relevant risk characteristics. In fact, those in the tenth decile have a loss ratio relativity almost 57% higher than the loss ratio relativity for the policies in the first decile. The results for homeowners insurance, shown on Exhibit 3b, demonstrate an even larger difference as the loss ratio relativity of the highest decile is 177% higher than the loss ratio relativity of the lowest decile.

Univariate Results

In addition to the overall model performance, results are also shown for each of the variables used in the model on a univariate basis. Standard automobile data is shown in Exhibit 4a and homeowners data is provided in Exhibit 4b. For each variable, loss ratio relativities are shown for relevant values of the variable, as well as the corresponding average score for those policies with that particular characteristic. This data further demonstrates that the variables considered by the ISM7 model have predictive power in identifying expected cost differences, and that the scores produced by the model show a pattern consistent with the univariate loss ratio results for each variable.

Additional Validation Results

Exhibit 5a and 5b contain validation results broken out separately by frequency and severity of loss. These results are based upon combined data from the holdout sample as well as the data used to build the model. For standard automobile, frequency and severity results have been combined across the four coverages included in the data set (bodily injury, property damage, collision and comprehensive). Frequency counts each claim by coverage as a separate claim and divides this number by the actual exposures for all four coverages combined. Severity is calculated by taking the total amount incurred across all four coverages, and dividing by the total number of claims, counting each claim by coverage as a separate claim. The homeowners data set does not include any losses related to catastrophe events. Consistent with other studies that have been done, the standard automobile data shows that the predictive nature of credit information is predominately found in the ability to segment risks based upon the frequency of loss. For homeowners insurance, the scoring model shows a strong relationship to both frequency and severity of losses.

Finally, standard automobile information by coverage is shown on Exhibit 6. This exhibit shows the ISM7 Model to be a valid predictor of loss potential for each of the major coverages.

Independent Statistical Assessment

To verify that there is a significant statistical correlation between the score developed by the ISM7 model, and the frequency of claims, the final ISM7 model was also the subject of an independent assessment. The assessment was performed by an employee of Allstate who was not involved in the development of the ISM7 model. This review was conducted by a fellow of the Casualty Actuarial Society with an extensive background in statistics, and who, although not involved in the development of this particular insurance scoring model, has extensive experience in the development of other insurance scoring models.

Methodology

The approach used in this assessment was to sort the data by IS score decile group, and test for statistically significant differences in average frequency by group. To do this, generalized linear models were fit with Poisson distributions and log link functions, using frequency as the dependent variable and IS decile group as the independent variable. Wald 95% confidence intervals around the expected frequencies by group were then estimated and any "overlaps" between the confidence intervals were further analyzed. The less "overlap," the more likely it is that frequency varies by IS score. A comparison of the actual distributions by number of claims to hypothetical Poisson distributions confirmed that the Poisson distribution is a reasonable approximation of the claim process. Expected frequencies and confidence intervals by group were estimated using the maximum likelihood method. For groups with nonzero overlap between the 95% confidence intervals, contrasts were used to estimate the probability that the true group frequencies might actually be the same.

Results, based on decile groups of equal volume are displayed for Standard Automobile data on Exhibit 7a, and for Homeowners data on Exhibit 7b. These results include estimated frequencies, confidence limits and chi-square significance tests.

Findings

For Standard Automobile, frequencies were evaluated for each of the following coverages; Bodily Injury, Property Damage, Collision, and Comprehensive coverages. Overall, the differences in group frequency were highly significant for each of the four coverages. The only material overlap was observed between the two best IS score groups for Bodily Injury and Property Damage coverages, which had around a 30% chance of coming from the same distribution. Differences in frequency between IS groups for Homeowners was also highly statistically significant. Therefore, this independent assessment reached the conclusion that there is a significant statistical correlation between the score developed by the ISM7 model, and the frequency of claims.

Adverse Action Reasons

When the ISM7 Model calculates a score that does not fall into the range of scores corresponding to the most favorable group, it also determines the most significant credit report attributes resulting in that higher score. This is done for each individual credit report used in calculating the ISM7 policy score, by comparing the points assigned for each specific variable in the model to the average number of points that are assigned to the group receiving the very best scores. The difference is then used to rank each variable in the order that it contributed to a higher score. Up to four reasons are recorded; however, only those variables for which the consumer's assigned points exceeded the average points of those with the very best scores would be considered as a potential adverse action reason. When two credit reports are used to arrive at a policy score, the reasons associated with the credit report which generated the higher score are reported as the adverse action reasons for the policy.

For each variable considered in the model a specific adverse action reason may be generated. We have examined standardized credit explanations provided by other modelers, including a consumer reporting agency and a third-party modeler, and have found that our reasons provide similar or more information to the reasons used by these other modelers.

The following is a list of potential reasons that may be used in connection with the ISM7 Model.

- The number of revolving accounts opened in the last two years: A revolving account is one in which you have the option to pay the balance off each month, or carry part of the balance over to the next month. Generally, if you have not opened a revolving account in the past two years, you may receive a more favorable insurance score. Please note that we do not consider car loans and/or mortgage-related accounts when determining the number of recently opened accounts.
- The number of installment accounts opened in the last two years: An installment account is an account with a fixed payment amount for the duration of the payment period. Generally, if you have not opened any installment accounts in the past two years, you may receive a more favorable insurance score.
- The number of revolving accounts that are currently between 60 and 120 days past due: A revolving account is one in which you have the option to pay the balance off each month, or carry part of the balance over to the next month. Generally, if you do not have any revolving accounts that are 60 days or more past due, you may receive a more favorable insurance score.
- The presence of a severely derogatory account within the past five years: A delinquent account is considered severely derogatory if it results in a repossession, a collection, or the account being charged off as a bad debt. Avoiding future delinquencies may lead to a more favorable insurance score.
- The presence of a collection within the past five years: When we refer to a "collection," this could include collections that were previously paid off or

collections on closed accounts. We exclude medical collections that are identified as such. Those with the most favorable insurance scores will typically have no collections on their credit report. Avoiding future collections may lead to a more favorable insurance score.

- The presence of at least one customer-initiated, bank-related inquiry on your credit report in the past two years: Inquiries appear on your credit report to show that credit grantors or other authorized parties have requested a copy of your credit report. Please note that we only consider customer-initiated inquiries, and we consider no more than one customer-initiated, bank-related inquiry during any 90-day period. Generally, fewer customer-initiated credit inquiries may lead to a more favorable insurance score.
- The presence of a derogatory item within the past five years: A derogatory item may include a delinquency, a collection, or a derogatory public record, such as a bankruptcy, judgment, lien, repossession, or foreclosure. Avoiding derogatory items in the future may lead to a more favorable insurance score.
- The presence of two or fewer accounts within the past five years: Generally, if you have three or more accounts on your credit report, you may receive a more favorable insurance score. However, having too many accounts may also adversely affect an insurance score.
- The number of accounts you have had open over the past five years: Generally, if you have fewer than 22 accounts on your credit report, you may receive a more favorable insurance score. According to your credit history, you have held 22 or more accounts within the past five years. Please note that even if an account is currently closed, we will still consider it if it was an open account during the past five years. Closing accounts will not necessarily improve an insurance score.
- The number of payments that were 30 days late in the past year: We consider payments that were 30 days late to be delinquencies. Even if the delinquency was later paid off, or if it is on an account that has since been closed, we still consider the delinquency when determining an insurance score. Generally, the more delinquencies you have on your credit report, the greater the effect it will have on your insurance score. Avoiding future delinquencies may benefit your insurance score.
- The number of open revolving accounts where the current balance you owe is greater than 75 percent of the largest balance you have owed for that account: Please note that this is not the limit available on the account, but rather the highest outstanding balance you have ever carried on that account. A revolving account is one in which you have the option to pay the balance off each month or carry part of the balance over to the next month. Generally, lowering the balances on revolving accounts with a large balance may lead to a more favorable insurance score.
- The presence of a derogatory public record item: A derogatory public record item could be a bankruptcy, judgment, lien, repossession or foreclosure from the last five years on your credit report. These types of public record items will have an adverse effect on an insurance score. This is true even if you subsequently satisfied the public record item. Avoiding future public record items may lead to a more favorable insurance score.

- The number of months since the most recent derogatory public record: A derogatory public record item, which includes items such as a bankruptcy, judgment, lien, repossession or foreclosure, will have an adverse effect on an insurance score. The more recent the public record, the more adverse the impact may be on an insurance score. This is true even if you subsequently satisfied the public record item. Avoiding future derogatory public record items may lead to a more favorable insurance score.
- The average number of months that accounts are listed on the credit report: Generally, the longer your average age of accounts, the more favorable your insurance score will be. Those with the most favorable insurance scores often have an average age of accounts of 14 years or longer.
- The number of months since the most recent delinquent payment: A delinquent payment is one made over 30 days late. Delinquent payments within the past five years may have an adverse effect on an insurance score and the more recent the delinquency, the greater the adverse effect. Please note that over time the impact of this type of delinquency on your insurance score will decrease and even disappear if there are no new delinquencies. Avoiding future delinquencies may benefit your insurance score.
- The number of months since the most recent customer-initiated bank or credit card inquiry on the credit report: The presence of customer-initiated bank or credit card inquiries on a credit report can adversely impact an insurance score. Inquiries appear on your credit report to show that credit grantors or other authorized parties have requested a copy of your credit report. The more recent the inquiry, the greater the effect it will have on your score. Please note that we only consider customer-initiated inquires, and we will consider no more than one customer-initiated, bank-related inquiry during any 90-day period. Generally, fewer customer-initiated credit card inquiries may lead to a more favorable insurance score.
- The amount of currently past due items: The presence of currently past due items on a credit report can have an adverse effect on your insurance score. The higher the amount past due, the greater the adverse effect may be. Reducing and eliminating past due amounts may lead to a more favorable insurance score. Those with the most favorable insurance scores will typically have no accounts with past due items.
- The percentage of active accounts with positive balances: While it is expected that a number of an individual's active accounts will have a balance, the fewer accounts carrying a balance, the more favorable an insurance score may be. Please note that paying off some accounts may lead to a more favorable insurance score.
- The number of recent customer-initiated, credit card inquiries on the credit report: Please note that we only consider customer-initiated inquiries within the last two years. Inquiries appear on your credit report to show that credit grantors or other authorized parties have requested a copy of your credit report. The greater the number of customer-initiated credit card inquiries, the greater the adverse effect on your insurance score. Generally, fewer credit card account requests may lead to a more favorable insurance score.

Exhibit 1a

STANDARD AUTO

Order of Significance Level of Entry
as Determined by Stepwise Regression Procedure
(Significance Level of Entry and Exit = 0.2)

The variables were entered in the following order. None were removed at a later stage of the stepwise regression.

Step	Variable Entered	C(p)	F-Value	Pr > F
1	Months since the most recent delinquency	1163.03	1974.95	<.0001
2	Number of bank inquiries in the past 2 years (considers no more than one bank inquiry within a 90-day period)	692.39	472.58	<.0001
3	Number of credit card inquiries	503.18	191.18	<.0001
4	Number of collections in the past 5 years	364.89	140.29	<.0001
5	Average number of months trades on file (excl auto and mortgage related trades)	287.82	79.06	<.0001
6	Presence of a derogatory item in the past 5 years (other than one 30-day late payment)	211.69	78.13	<.0001
7	Number of open revolving trades >75% of high credit amount	157.29	56.39	<.0001
8	Number of derogatory public records in the past 5 years	111.16	48.13	<.0001
9	Revolving trades currently 60 to 120 days past due	78.20	34.95	<.0001
10	Presence of a severly derogatory trade in the past 5 years	63.81	16.40	<.0001
11	Percent of active trades with a positive balance	52.17	13.63	0.0002
12	Installment trades opened in the Past 2 Years (excl auto and mortgage related trades)	42.88	11.29	0.0008
13	Months since the most recent derogatory public record	35.72	9.16	0.0025
14	Amount currently past due	30.58	7.14	0.0075
15	Months since the most recent bank or credit card inquiry	27.71	4.88	0.0272
16	Revolving trades opened in the Past 2 Years (excl auto and mortgage related trades)	25.85	3.85	0.0497
17	Number of trades in the past 5 years	20.34	7.51	0.0061
18	Number of payments 30 days late in the past year	19.00	3.34	0.0675

Note: No variables were removed by the stepwise procedure (using entry and exit level of significance of 0.2).

Exhibit 1b

HOMEOWNERS

Order of Significance Level of Entry
as Determined by Stepwise Regression Procedure
(Significance Level of Entry and Exit = 0.2)

The variables were entered in the following order. None were removed at a later stage of the stepwise regression.

Step	Variable Entered	C(p)	F-Value	Pr > F
1	Presence of a derogatory item in the past 5 years (other than one 30-day late payment)	858.87	1059.74	<.0001
2	Number of bank inquiries in the past 2 years (considers no more than one bank inquiry within a 90-day period)	494.89	365.94	<.0001
3	Number of collections in the past 5 years	304.74	192.15	<.0001
4	Number of credit card inquiries	200.50	106.23	<.0001
5	Months since the most recent delinquency	128.29	74.21	<.0001
6	Number of derogatory public records in the past 5 years	88.90	41.38	<.0001
7	Average number of months trades on file (excl auto and mortgage related trades)	53.34	37.56	<.0001
8	Revolving trades currently 60 to 120 days past due	30.34	25.01	<.0001
9	Presence of a severly derogatory trade in the past 5 years	22.03	10.30	0.0013
10	Amount currently past due	15.16	8.87	0.0029
11	Installment trades opened in the Past 2 Years (excl auto and mortgage related trades)	12.77	4.39	0.0362
